Vitamins for His Royal Highness

Children are entitled to every advantage that medical science can give them toward creation and maintenance of robust health. Vi-Penta Drops, the Roche "easy-to-take" vitamin preparation, offers a definite advantage in vitamin medication for infants and children who cannot or will not take capsules. Vi-Penta Drops contain generous quantities of vitamins A, B₁, B₂, C and D, and may be added to milk, cereals and other foods without affecting the flavor or being detected. The Vi-Penta preparations (Drops and Perles) are advertised to the laity. HOFFMANN-LA ROCHE, INC. • ROCHE PARK • NUTLEY, NEW JERSEY

VI-PENTA DROPS 'ROCHE'

Saw you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

Calcium and Vitamin D

in pleasant-tasting, easy-to-take form—

CALCI-DELTA TABLETS

(Dicalcium Phosphate and Vitamin D)

TO MEET the exceptional metabolic demands for calcium made upon the body at certain times—during pregnancy, lactation, early childhood—Lederle now makes available “Calci-Delta Tablets Lederle.” These new tablets serve as an excellent source of calcium, phosphorus and Vitamin D. They are easily chewed and swallowed and their pleasant flavor disguises the rather disagreeable taste typical of calcium salts.

If the mother does not receive an adequate calcium, phosphorus and Vitamin D intake during pregnancy and lactation, either in the diet or in supplements thereto, she may suffer from tooth decalcification and other forms of calcium deficiency. Likewise, the fetus may be adversely affected, if enough of these elements are not supplied for its structural growth. “Calci-Delta Tablets Lederle” are in a palatable form, which makes them appreciated by pregnant and lactating women.

“Calci-Delta Tablets Lederle” are also especially suitable for children to prevent rickets and promote normal tooth and bone development in early childhood.

Literature on request

...for close-ups of **NICOTINE TOLERANCE**

INCONCLUSIVE symptomatology constantly challenges the physician's resources. If the patient smokes, a check-up on nicotine intake may be in order.* But this is a problem in itself, considering the reluctance of smokers to accept adjustments of tobacco usage.

Slow-burning Camel cigarettes provide an answer. They are the voluntary choice of millions and millions of smokers who appreciate distinctive mildness and mellow flavor, Camel's famous "pleasure factor." Your patient's enthusiastic acceptance of Camels will help to assure more reliable data for case histories, a big advantage when analyzing such cases by groups.

**J.A.M.A., 93:1110—October 12, 1929*

In Cholecystitis

The intensified flow of thin liver bile produced by Decholin (dehydrocholic acid) encourages removal of inspissated accumulation from the bile passages and facilitates biliary tract drainage. Subjective relief usually follows its administration; not infrequently corrective improvement is discernible roentgenologically.

Jenkinson, observing the influence of Decholin in chronic cholecystitis, states: "There was usually a marked improvement of the symptoms following medical management including dehydrocholic acid (Decholin)."¹

Decholin is contraindicated in complete obstruction of the common hepatic bile duct.

Riedel - de Haen, Inc. New York, N. Y.

Decholin

For Safe Effective Antisepsis Without Pulmonary Complications

The fact that ARGYROL has been used repeatedly and with good effect in the broncho-copic irrigation of the lungs is striking evidence of its freedom from any tendency towards pulmonary complications.

But this is only *one* of ARGYROL's many unique advantages. For ARGYROL is *not* just another "germ-killer." It is peculiarly adapted to the treatment of mucous membrane infections. It not only attacks the infectious organisms directly but many writers have observed that it appears to aid and abet the natural defensive mechanisms of the tissues. It promotes a decongestion and circulatory stimulation without resort to powerful vasoconstriction. It stimulates the mucous

glands so as to effect "a physiologic washing of the membrane." It produces no ciliary injury. It is detergent and inflammation-dispelling. And above all, it remains bland and non-irritating in all concentrations from 1% to 50%. Some explanation of ARGYROL's superiority in these respects is likely to be found in its controlled pH and pAg, its fine colloidal dispersion, its more active Brownian movement.

This is why ARGYROL, in over 40 years of world-wide use, has established an unparalleled record of clinical efficiency and safety. Specify genuine "ARGYROL Barnes in Original Package" whenever ordering, prescribing, or recommending.

ANTISEPTIC EFFICIENCY PLUS

- SOOTHING AND INFLAMMATION-DISPELLING PROPERTIES
- NO CILIARY INJURY—NO TISSUE IRRITATION
- NO SYSTEMIC TOXICITY
- NO PULMONARY COMPLICATIONS
- DECONGESTION WITHOUT VASOCONSTRICTION

Military Footwear Prescription Fittings

During the First World War, Pediforme Footwear, favorably reported by the Surgeon General's Office, became the Prescription Routine of surgeons, orthopaedists, physicians who still insist on them. In the present War, Pediforme provides the military and non-military doctor with the proved and approved Prescription Fittings in Official Styles for all Services.

THE CAUSE *Obscure*

"The ultimate cause of peptic ulcer is unknown..."

Winkelstein, Asher: Rev. Gast.

May-June, 1942, p. 174

THE TREATMENT *Clear*

"Aluminum hydroxide... appears to be the most effective drug yet found for controlling severe cases of peptic ulcer during a period of acute activity."

Emery, E. S. Jr., and Rutherford,

R. B.: New Eng. Jnl. Med.

Feb. 8, 1940

CREAMALIN

REG. U. S. PAT. OFF.

Brand of Aluminum Hydroxide Gel

WHAT IT OFFERS

- approximately 5.5% aluminum hydroxide
- antacid action of 12 times its volume of N/10 HCl in less than 30 minutes (Toepfer's reagent)
- non - alkaline; non - absorbable; non-toxic
- no acid rebound; no danger of alkalosis
- prompt and continuous pain relief in uncomplicated cases
- rapid healing when used with regular ulcer regimen
- mildly astringent, demulcent

NEW YORK, N. Y.

Another Year of Research i

During the year 1942, the results of distinct research projects covering different phases of ERTON therapy have been added to the extensive bibliographic background of this important therapeutic measure.**

STECK, I. E.: *"Further Clinical Experience in the Treatment of Arthritis with Vitamin D,"* *Ohio St. Med. J.*, 38:440-443, May, 1942.

Steck reported on his clinical experience in 98 cases of arthritis treated with ERTON and no concurrent medication.

These patients were observed over a period of years at the Arthritis Clinic, Research and Educational Hospitals, University of Illinois.

The therapeutic results were closely comparable with those previously reported from the same clinic. (Dreyer, I., and Reed, C. I.: "Treatment of arthritis with massive doses of Vitamin D," *Arch. Phys. Ther.*, 16:537, 1935; Reed C. I., Struck, H. C. and

Steck, I. E.: "Vitamin D: Chemistry, Physiology, Pharmacology, Pathology, Experimental and Clinical Investigations," University of Chicago Press, p. 389, 1939.)

In addition to the beneficial therapeutic effect of ERTON, it is important to note that "there was no toxicity at any time among the 98 patients included in this report."

INYDER, R. G., SQUIRES, W. H., FORSTER, J. W., TRAEGER, C. H. and WAGNER, L. C.: *"Treatment of 200 Cases of Chronic Arthritis with Electrically Activated Vaporized Sterol (Ertron),"* *Indus. Med.*: 11:295-316, July, 1942.

The authors made a comprehensive study of 200 cases of chronic arthritis treated with ERTON. Most of these patients had been treated previously by other methods at the same clinic (Arthritis Clinic, Hospital for Ruptured and Crippled, New York City) without success.

After extensive laboratory and clinical observations, the authors reported that "the medication used is a relatively non-toxic therapeutic agent. In our experience it has definite value as a method of treating chronic arthritis, especially of the rheumatoid type."

REYNOLDS, C.: *"Comparative Therapeutic Value and Toxicity of Various Types of Vitamin D,"* *Journal-Lancet*, 62:372-375, Oct., 1942.

Reynolds compared the therapeutic value and toxicity of various forms of Vitamin D, and concluded that massive doses of irradiated ergosterol bring about the development of toxic effects without clinical improvement of arthritic patients, while use of the electric-discharge activated heat-vaporized ergosterol (Whittier Process) has consistently been followed by clinical improvement with frequent rehabilitation, and with negligible or no toxic manifestations even over prolonged periods of intensive treatment."

ERTRON THERAPY

These important contributions to the literature emphatically demonstrate that *Ertronization* is a rational therapeutic measure in the treatment of arthritis, based on two outstanding features:

I. Clinical Response

2. Safety

ERTRONIZE YOUR ARTHRITIS PATIENTS

ERTRON—the only high potency, activated, vaporized ergosterol (Whittier Process)—
is made only in the distinctive two-color gelatin capsule.

INCREASING INTEREST IN CLINITEST

The New 1-Minute Tablet Test for Urine-Sugar

① IN THE LABORATORY

② IN THE HOME

③ IN THE OFFICE

The invariable reaction to a demonstration of Clinitest is one of wonder that so *dependable* a test method could, at the same time, be so *simple* and so *speedy*.

Naturally this has been reflected in a rapidly increasing demand for Clinitest Sets.

Some Advantages which Offer Special Appeal

No external heating required • Active reagents in a single tablet • Standard fool-proof technic • Dependable—closely approximates Benedict's, Fehling's, Haines' tests • Indicates sugar at 0%, $\frac{1}{4}$ %, $\frac{1}{2}$ %, $\frac{3}{4}$ %, 1% and 2% plus.

TEST INVOLVES 3 SIMPLE STEPS

- ① 5 drops urine *plus* 10 drops water
- ② Drop in tablet
- ③ Allow for reaction and compare with color scale

Available through your prescription pharmacy. Write for full descriptive literature.

The Popularity of

THE SODATE (*Brewer*)

(the original enteric-coated tablet of Theobromine Sodium Acetate)* is due to three factors:

- 1. IT IS CLINICALLY PROVED.**
- 2. IT IS EFFECTIVELY ENTERIC COATED.**
- 3. IT IS DECIDEDLY LESS EXPENSIVE.**

Indicated in treatment of coronary artery disease, edema and hypertension.

Dosage: One 7½-grain tablet four times a day, before meals and upon retiring.

Available on prescription in 7½-grain tablets, with or without Phenobarbital (½ grain), or 3¾-grain tablets, with or without Phenobarbital (¼ grain), and Theobromine Sodium Acetate 5 grs. with Potassium Iodide 2 grs. and Phenobarbital ¼ gr., 100 per bottle.

* Capsules are now available for those few patients who need extra medication.

FEAR OF THE UNKNOWN

Far or extreme apprehensiveness are conditions that must be dealt with in the anxiety of surgical patients, especially the younger ones, and for this reason pre-operative sedation is generally a desirable measure. 'Delvinal' Sodium Vinbarbital Sodium has proved exceptionally useful for this purpose, inducing a *smooth* transition from tense wakefulness to restful quiet and sleep.¹

When 'Delvinal' Sodium is administered preoperatively, the amount of anesthetic may be reduced by one-quarter or one-third, and the incidence of vomiting is lowered.² Moreover, by means of 'Delvinal'

Sodium, amnesia and rest may be obtained postoperatively, and other advantages associated with the use of this preparation in surgical anesthesia are economy of time, and opiates.

'Delvinal' Sodium is also indicated for the relief of functional insomnia and various psychiatric conditions, as well as for obstetric sedation and amnesia.

Supplied in dry-filled capsules of three strengths: $\frac{1}{2}$, $1\frac{1}{2}$ and 3 grains.

CLINICAL VALUE OF MUSCLE EXTRACT

Carnacton

IN

**ANGINA PECTORIS
ARTERIOSCLEROSIS
OBLITERATIVE ARTERIAL DISEASES**

Carnacton is a biologically tested extract of *diaphragm muscle* — a powerful, markedly vascularized muscle with a high metabolic rate — most effective for its purpose. Carnacton is not only a vasodilator but also promotes cardiovascular tone and vigor.

In 1 cc. and 2 cc. ampuls — boxes of 12 and 50; vials of 30 cc. for oral use *Send for professional brochure.*

CAVENDISH PHARMACEUTICAL CORP., 25 West Broadway, New York

Safeguarding

YOUR USE OF

BENZEDRINE SULFATE TABLETS

Any potent drug should be administered under medical supervision, and Benzedrine Sulfate* is no exception.

In medical literature, the majority of the reports of undesirable reactions attributed to Benzedrine Sulfate have been traceable to cases of indiscriminate or unsupervised use. This is equally true of the often magnified and sensational reports in the lay press.

Obviously, these unfavorable reports greatly retarded the wider clinical use of this valuable therapeutic agent. From the very beginning, Smith, Kline & French Laboratories—as a matter of business judgment, to say nothing of ethical considerations—did what it could to keep Benzedrine Sulfate solely in the hands of the medical profession.

But our own unaided efforts never met with complete success. And, understandably concerned over the possibility of self-medication, certain physicians hesitated to employ Benzedrine Sulfate therapy.

However, when the Federal Food, Drug & Cosmetic Act of June, 1938, became effective, we immediately put Benzedrine Sulfate in the category of drugs to be sold on prescription only. The Act is strictly enforced and is supplemented by similar legislation in many states. Today, as a result, the physician can prescribe Benzedrine Sulfate, secure in the knowledge that there is little likelihood of its abuse.

**Brand of amphetamine sulfate*

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA,

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

"AT LEAST 3 NUTRITIONAL ESSENTIALS DESERVE SPECIAL EMPHASIS IN CHILDHOOD"

PROTEIN—

"A quart of milk daily supplies most of the protein need of the young child and half the need at the beginning of adolescence."

CALCIUM—

"Calcium is the mineral requiring chief attention in childhood, since the other essential minerals are more likely to be present in sufficient amount in most diets... "Milk and milk products are our best food sources of calcium."

VITAMIN D—

"... is required throughout the growth period, a fact extensively overlooked."

A pleasant, convenient and more easily digested method of meeting this desired intake of the three nutritional essentials is provided in

HORLICK'S FORTIFIED

Prepared with milk, Horlick's is rich in protein, calcium and moreover is enriched with Vitamins A, B₁, D and G.

SEARLE
Research..

Glandular Extraction Unit Used in Preparation of Gonadophysin. This Apparatus is Refrigerated to Maintain the Contents at Temperatures near Freezing.

Improved Pituitary Gonadotropic Hormone

Several years of research and manufacturing effort were expended by Searle investigators in developing a product which would provide the medical profession with the pituitary gonadotropic hormone in stable and potent powder form—a definite improvement over the ampul solution form which undergoes a relatively rapid deterioration and proportionate loss of potency.

GONADOPHYSIN

**Improved Gonad Stimulating Factor
(Fresh Gland Extract)**

provides, in dry form, full potency and stability. It contains both the Follicle Stimulating Hormone and the Luteinizing Hormone. Its action is the stimulation of gonadal function

Gonadophysin encourages a physiologic ratio between estrin and progestin production and consequently is valuable in menorrhagia and functional uterine hemorrhage, amenorrhea, dysmenorrhea and oligomenorrhea, including hypovarianism as seen in functional menopause.

How Supplied: Packages of three serum-type ampuls, each containing 500 Rat Units of powdered hormone, and accompanied by three 5 cc. ampuls of Sterile Solution for dissolving Gonadophysin. Administration is by intramuscular injection.

The Moving Finger Writes

OF MORE NORMAL, HAPPIER PEOPLE

THE oscillating "finger" of the electroencephalograph, recording abatement of abnormality of brain waves, tells but a part of the story of epilepsy treatment with Dilantin⁺ Sodium. Fewer and less severe seizures, more normal social and economic life have been observed in many thousands of epileptic patients receiving this modern anticonvulsant.

Dilantin Sodium possesses "many advantages" in the control of epileptic convulsions.¹ For one thing it is, in many cases, superior in anticonvulsant effectiveness to phenobarbital or bromides, and—highly important—it is practically non-hypnotic. The inclusion of Dilantin Sodium (diphenylhydantoin sodium) in the new U.S.P. XII speaks volumes for its therapeutic importance.

That was not an idle promise—

when, during the halcyon pre-war days, buyers of G-E x-ray and physical therapy apparatus were assured of maintenance and technical service throughout the life of the apparatus. ¶ To make good that promise—despite trying difficulties which the war now imposes—G.E.'s branch offices and service depots continue to function throughout the United States and Canada. ¶ Of course, it isn't possible for the local G-E service man to call as often as heretofore, what with rationed tires and gas and other transportation problems. But he is always available when there is need for service on equipment. In fact, he feels that the most important part of his job these days is to help keep G-E equipment in the best possible operating condition, for the busier-than-ever physicians' offices, clinics, and hospitals in his territory. *He will not let you down!*

Today's Best Buy — U.S. War Bonds

The criterion of efficacy adhered to in the recent clinical investigation by Reynolds, Wilkey, and Choy,* at the Cook County Hospital, Chicago, was as follows:

"To consider pyridium therapy effective, alleviation or complete absence of symptoms had to occur within seven days."

Response of symptoms to Pyridium therapy in the 183 cases of common urologic conditions studied in this series was as follows:

PAIN	47 Cases	68.2% Improved
BURNING	116 Cases	84.5% Improved
DYSURIA	38 Cases	47.0% Improved
FREQUENCY	99 Cases	54.5% Improved
URGENCY	17 Cases	59.0% Improved
HESITANCY	20 Cases	85.0% Improved
NOCTURIA	77 Cases	53.0% Improved
PYURIA	55 Cases	76.5% Improved
HEMATURIA	7 Cases	100% Improved

These results afford additional confirmation of the many published reports on the clinical efficacy of Pyridium in producing prompt symptomatic relief in common urogenital infections.

Editorial

War and Social Reform

For those who still question the profound nature of the social and economic upheaval which is at the root of the present global war, the "Beveridge Report," a 100,000-word document compiled by Sir William Beveridge, noted English economist, will be an eye-opener. It would seem to be an important social document proposing, according to the *New York Times*,¹

"... complete and compulsory state insurance against every form of personal want and insecurity, to be administered by a Minister of Social Security and applied without regard for sex, age, income, or job. . . .

"An automatic product of Sir William's sickness plan will be the creation of a nationalized and completely comprehensive medical service for all citizens. This would broaden the present State panel of doctors into a revolutionary unified machine covering hospital, specialist, and surgical treatment and prenatal and postnatal treatment and convalescence."

Incidentally, the total cost is estimated at about \$4,000,000,000 yearly, or \$89 per capita. If adopted, it would affect the lives of 45,000,000 British people profoundly. It would naturally and automatically create a completely nationalized system of medical service.

Basically, it proposes to extend the social security program that has been operative in Great Britain for more than twenty-five years.

"Each type of social security presents its own special problems and pitfalls. People may easily become indifferent about a job if the con-

ditions and benefits of unemployment insurance are made more attractive than the job itself. Insurance against certain hazards, in short, sometimes increases the hazards themselves. This is the sort of question that must be raised regarding Sir William's proposals on unemployment benefits. If our future social programs are to be large-hearted, they must also be hard-headed, and they must undergo realistic analysis before they are accepted."¹

The report, though startling in the magnitude of its proposed cost and somewhat Utopian in its general concept and coverage, is indicative of a trend which cannot be ignored, and should not be minimized. One of the implements of social security is the practice of medicine, since illness and disability are prime causes of insecurity. Recognizing that fact, the *JOURNAL* in 1941 commented frequently upon the progress of the New Zealand experiments in compulsory health insurance.² In 1942, we published a brief editorial summarizing the *Draft Interim Report* of the British Medical Association, which studied "wartime developments and their effects on the country's medical services."³ We pointed out the fact that there is now developing here a distinct challenge to the resourcefulness and fluidity of organized medicine.⁴

"We cannot hold back," said Dr. W. G. Cottis, "the stream of world-wide changes by standing pat. If we are to escape regimentation we must prove that we ourselves can and will meet every

legitimate demand for service in the field of medicine."⁵ To this end, he proposed an extension of medical service by the State of New York in the following ways: more hospitals for the care of cancer patients; extension of laboratory facilities; provision of diagnostic clinics in general medicine; more convalescent homes; more district or county health units.

Under the impact of war and the profound economic and social changes which follow in its train, it would indeed be surprising if proposals somewhat similar to the "Beveridge Report" did not arise here in the course of time. We, like the English, and, earlier, the Russians, are seemingly irrevocably embarked upon the road of social reform. It is quite possible, since social reform is not wholly free from purely human frailty and error, that the control of medical practice may pass into the hands of others than physicians. The manpower question and the distribution of medical personnel may well prove to be the crucial issue which will determine at least for the duration, and possibly thereafter, the character and course of medical practice in this country.

These issues involve many questions of individual and state's rights; they challenge the education laws of many states; they challenge the ingenuity, the patience, and the wisdom of many agencies of government, of medicine, of private enterprise of all sorts. Their proper solution would seem to call for cool hard-headedness, free debate, and a thorough understanding of the objectives sought. Issues of this sort cannot in the

nature of human affairs be completely divorced from political considerations. In the minds of many physicians, politics is synonymous with obliquity and broken promises; with exploitation of minorities; with the *argumentum ad hominem*. To most politicians the physician might seem to be a good egg but odd—definitely odd. It's all in the point of view. These differing opinions must nevertheless be somehow reconciled to a set of principles which can be made to work in the public interest.

Since to define these principles it is necessary to know where we are going in the matter of social and economic reform, it would seem to us to be the prime obligation of those responsible for them to state clearly and as simply as possible the objectives, if they know what they are. After these are stated if not comprehensively, at least comprehensibly, it seems then the obligation of medicine to revise such of its structure as needs revision so that it may fit workably into the new scheme of things. To plunge blindly in the dark does not seem to us who are immediately and responsibly concerned with the public and private health of the nation to be a proper way to approach reform of any sort whatever. War or no war.

Virus Pneumonias

The problem of pneumonias due to bacterial agents, although not completely solved, has nevertheless been gratifyingly modified in the majority of pneumonia patients. The causative organism can usually be demonstrated in the sputum or from nasopharyngeal cultures; the clinical and x-ray pictures have been well defined, and a definite regimen of treatment by chemotherapy and other measures has been standardized. The improvement in the prog-

nosis of bacterial pneumonias has been one of the most satisfying features of modern medicine.

A familiar pneumonic syndrome, strikingly different from the above, has been reported in the literature with increasing frequency.^{1,2,3,4,5} The following are some details in which this "atypical" pneumonia differs from the ordinary or classic pneumonia:

The incubation period may be longer, some-

times as long as two weeks. The cough is unproductive and apt to assume a hacking nature. The temperature curve is more irregular, rises slowly, and falls by lysis in from a few days to two to three weeks. Headache, photophobia, and sweating are frequent concomitant symptoms. The leukocyte count is essentially normal. No bacteria found in the sputum or rhinopharynx can be associated with the disease. The pneumonic signs and x-ray picture are those of scattered infiltrations, often of a migratory nature. Sulfonamide therapy is futile; complications are unusual; and the mortality is low. In the few autopsies reported, the histologic reaction of the involved lung has been composed chiefly of mononuclear cells, and no bacteria have been found.⁴ Cytoplasmic inclusion bodies have been observed in the lungs of infants dying of this form of pneumonia.⁵ Because of the atypical clinical and x-ray findings, the pathologic reports of a mononuclear reaction in the areas of pneumonitis, and the resemblance of this response to the pneumonias caused by known virus agents, the term "virus pneumonia" has been suggested for this peculiar but definite pneumonic syndrome.^{3,5}

Attempts to find the direct causative agent in such pneumonias have led to the isolation of a virus which differs from the previously known influenza virus.⁶ Further research into the virus that causes this form of pneumonitis, by means of immunologic studies and neutralizing tests, has brought to light a re-

markable cross relationship between this pneumonic virus, or viruses, and those of psittacosis, meningopneumonitis, and lymphogranuloma venereum.⁷ This opens a fascinating field in the study of pneumonias and their relationship to contagion to and from animals, including household pets.

Suffice it to say that it is of the utmost importance to be able to recognize or suspect this pneumonic syndrome and its epidemiologic implications. A simple, confirmatory test may be the demonstration of inclusion bodies in the large mononuclear cells in the stained sputum of patients who have this disease.⁵ One of the sulfa drugs may be employed, with the thought of preventing secondary invasions, which are not uncommon in influenza pneumonia.⁸ If a short period of observation reveals no effect from the drug, it is wise to discontinue its use; otherwise toxic effects may ensue, to the detriment of the patient's condition.

"Our Hearts Were Young and Gay"

This engaging title, which appeared in the December, 1942, issue of the *Readers Digest*, caught our editorial attention. We read the article. It is a condensation from the book of Cornelia Otis Skinner and Emily Kimbrough. We hope that every doctor who reads our JOURNAL will take time to read that article* if not the book itself. We think it is the most inspiring human-life article that it has been our privilege as doctors to have read in many a long day.

We realize that this enthusiastic and superlative statement about an article in a non-medical magazine which tells about certain people and their personal experiences in England and France—with only a slight touch on

disease—is quite a bit out of the "ordinary," as the English say, to be recommended by medical editors. Therefore, we must state our reasons for this advice.

Our explanation is that we regard the story told in this article as of prime importance to every practicing physician in this country and the countries allied in this war. It shows some of the beauties of human life that existed before the present war started, in the most inimitable fashion that has ever been put forth in type—as we see it. It shows, too, as we see it, the color, the flavor, the humor, the beauty of life that the allied countries should seek to spread all over the world when this war has been won on the basis of the four freedoms.

Is this of interest to doctors of medicine?

* *Readers Digest*, December, 1942, page 149.

Yes, because mental and emotional health of their patients, as well as physical health, is what men and women over the ages have become physicians to secure for people.

Correspondence

OFFICE FOR EMERGENCY MANAGEMENT
WAR MANPOWER COMMISSION
WASHINGTON, D. C.

December 16, 1942

Dr. Peter Irving
292 Madison Avenue
New York, New York

Dear Doctor Irving:

The Directing Board of the Procurement and Assignment Service suggests that you publish the following statement on the cover page of the next issue of your JOURNAL, or in some other prominent position. The Board deeply appreciates the support, help, and cooperation always received from you:

"It is of the utmost importance that the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians, immediately have the name of any doctor who really is willing to be dislocated for service, either in industry or in overpopulated areas, and who has not been declared essential to his present locality. This is necessary if the medical profession is to be able to meet these needs adequately and promptly. We urgently request that any physician over the age of 45 who wishes to participate in the war effort send in his name to the State Chairman for the Procurement and Assignment Service in his state."

Sincerely yours,

FRANK H. LAHEY, M.D., *Chairman,*
Directing Board

Procurement and Assignment Service for
Physicians, Dentists, and Veterinarians

Syracuse, New York,

Chairman of Subcommittee on Scientific Exhibits of the Convention Committee.

The Annual Meeting will be held May 3-6, 1943, Hotel Statler, Buffalo, New York.
The list will be closed on February 15, 1943.

PETER IRVING, M.D., *Secretary*

EPICONDYLITIS HUMERI

K. G. HANSSON, M.D., New York City

EPICONDYLITIS is often erroneously spoken of as "tennis elbow." Epicondylitis humeri, properly defined, is a clinical entity with marked pain and tenderness about the epicondyle of the humerus and inability to make a tight fist or raise any weight with the forearm in pronation. It occurs after muscular exertion such as playing tennis, squash, badminton, polo, baseball, etc., or after some continuous labor, such as type-writing, bricklaying, painting, pressing clothes with heavy irons, and the like. Therefore, play or work entailing repeated pronation and supination of the forearm with the elbow extended, or repeated extension of the wrist, seems to run through the history of all patients who have the above complaints.

History

Epicondylitis has been the subject of investigation at least since 1896, when Bernhardt published a paper on a little-known form of occupational neuralgia. Osgood published an article on radiohumeral bursitis in 1922.¹ He removed the bursa in 3 cases, with indifferent results. Hohman, in 1927,² advocated rest for what he called tennis elbow. Cyriax, in 1936,³ and Mills, in 1937,⁴ advocated manipulation for the treatment of epicondylitis. Horwich and I, in 1930,⁵ reported 16 cases that were cured by immobilization with a cocked-up splint of the wrist. I had become interested in epicondylitis several years before because many of these cases were referred to me for physical therapy. The results obtained by various treatments were very unsatisfactory. In reviewing the literature, one is somewhat confused because all writers have not confined themselves to epicondylitis alone but have brought into the discussion almost all possible pathologies of the elbow. It therefore is important to define clearly the subject for our discussion. We shall exclude such pathologies as arthritis, peri arthritis, neuritis, neuralgia, and direct trauma, and confine ourselves to two varieties of epicondylitis—the *acute* or *subacute* type, from indirect trauma following athletic games (usually found in young, active people with hypertrophy of the muscles in the forearm),

and the *occupational chronic* type, found in older patients as a result of long-continued stress and strain on the extensors of the wrist and fingers.

Anatomy and Physiology

The interesting feature of the skeletal anatomy of the elbow and forearm is the marked degree of supination and pronation between the radius and the ulna. This is essentially due to the small, round head of the radius articulating with the proximal end of the ulna. These two bones are held so firmly together by tendinous and ligamentous structure that dislocations between them are practically unknown. In fact, the head of the radius will fracture before it will dislocate. The muscles concerned in this region take their origin from the condylar ridge and the external condyle of the humerus. These muscles, as they take their origin from above downward, are the brachioradialis or supinator longus, the extensor carpi radialis longus and brevis, the extensor digitorum communis, the extensor carpi ulnaris, and, distally, the anconeus. Beneath the conjoined tendon of these muscles is the supinator radii brevis.

These muscles receive their nerve supply from the radial nerve by means of branches that come off above the epicondyle. The sensory nerve supply also comes from the radial nerve. Most of these muscles are of the quick-action type, with relatively short muscle belly and long, slender tendon; but it is not generally realized how extensive the elasticity is in these muscles.

Six normal individuals measured from the external epicondyle to the tip of the middle finger—i.e., the length of the extensor digitorum communis in its maximum and minimum length—will show an average difference of 8.4 cm. This seems of importance because if a muscle is stretched 8.4 cm. and in addition is called on to receive a severe blow, something is apt to break.

Furthermore, in supinating the forearm, the head of the radius acts as a fulcrum, with the short lever from the head of the radius to the epicondyle on one side and the long lever from the head of the radius to the hand on the other side—or what is called a lever of the first order. This relation is about 1 to 10. Here lies a great disadvantage in

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1942.
From the Department of Surgery, New York Hospital-Cornell Medical College.

the mechanism of the elbow, the forearm, and the hand. Everything tends to give the epicondyle the short end, so to speak.

Phylogenesis.—If the human body is regarded as a living organism which has developed from a more primitive mechanism to a more and more complicated one, this change must be assumed to have been accomplished not overnight but over a long span of years.

In the vegetable kingdom, motion is a curiosity. The lower animals of the ameba class probably represent the most primitive activity, and as one goes up the evolutionary ladder he finds that certain of our present movements developed earlier than others. The characteristic in all of these early motions is that they are movements toward the center of the body; i.e., flexion and adduction—pronation and inversion. The nerve supply even in the embryonal stage of these muscles, which brings parts of the skeleton toward the center, is earlier and more easily distinguished than the corresponding nerves to muscles performing movements away from the body; i.e., the extensors and abductors. Because most of our work and exercises are movements toward the body, we have developed the flexors and adductors to a greater power than we have the corresponding extensors and abductors. This is demonstrated by comparing, for instance, the flexor and extensor strength of the fingers and toes, or the strong adduction in the shoulder and hip, with the comparatively weak abduction in the same joints.

If this phylogenetic study is applied to the flexors and extensors of the wrist and fingers and to the pronation and supination of the forearm, it will be found that the muscles arising from the internal epicondyle of the humerus are much stronger than those coming from the external epicondyle. Hand in hand with the phylogenesis of muscles goes the specific morbidity. By this we mean that the phylogenetically older muscles are less subject to pathologic change. In this connection one may recall the prevalence of dropwrist and dropfoot in peripheral neuritis, the attitude of the forearm and the hand in cerebral hemiplegia, and the common pathologic involvement of the deltoid muscles and the gluteus medius and maximus as compared with the corresponding adductors and flexors. It is therefore only rational to state that the external condyle of the humerus gives origin to phylogenetically young muscle, with corresponding specific morbidity.

When in our present-day activity, whether in sport or in work, our lately acquired ex-

tensors and supinators are called on for sudden feats of strength or long-continued work, these structures are apt to give way. Examples of this specific morbidity are deltoid myositis and myositis of the trapezius muscles, the lumbar muscles, and the gluteus medius. To this group belongs, undoubtedly, epicondylitis humeri.

Locus Minoris Resistentiae.—The question to be answered next is, Where does a muscle give way first? Or, in other words, Where is the weakest part of a muscle? Is it the bony connection or the point at which muscle tissue changes into connective tissue to form tendon? To solve this problem we performed a simple experiment on a rabbit. Under ether anesthesia the gastrocnemius muscle was dissected out. In the rabbit this is a relatively powerful muscle, with short muscle belly and long tendon. When the maximum pull is exerted on this muscle and then the point of physiologic extension is overstepped, a tear results, and this invariably took place at the bony connection and not in the muscle tissue, in the tendon, or where muscle fuses into tendon.

It seems rational to assume that the locus minoris resistentiae for a muscle is not the muscle itself but the point where it is fixed on the skeleton. We therefore thought that it would be possible to find some roentgen evidence; but after studying a number of anteroposterior and lateral views of patients with epicondylitis, we were disappointed. However, by taking oblique roentgenograms, tilting the x-ray tube 45 degrees, we were able to find a shadow over the epicondyle which was very suggestive of an avulsion in some cases.

Symptoms

Pain is the outstanding symptom. It seldom comes on directly after physical exertion, but the onset is gradual. *Traumatic epicondylitis* is characterized by pain over the lateral elbow when a tight fist is made, when indulging in a favorite sport, or even when lifting light objects, such as a glass of water. The pain is either sharp and lancinating or a dull ache. It is present when lifting is done with the forearm in pronation, and it is usually absent when lifting is done with a supinated forearm. There is no pain on resting. The area of tenderness varies. It may be located over (1) the distal end of the lateral epicondyle or (2) the posterior surface of the epicondyle. More commonly, the maximum tenderness is over (3) the anterior surface of

the epicondyle, (4) the radiohumeral joint line, (5) the radio-ulnar joint, or sometimes (6) the proximal epicondyle. The patient is usually well aware of the point of tenderness and can show it readily. It can easily be elicited by completely extending the elbow, by making a tight fist, or by extending the wrist against resistance. Some tenderness is often found over the extensor muscle group of the forearm. In *occupational epicondylitis* the pain is usually a dull ache, which is not present on rest but is always at its maximum when the patient is working at an occupation that consists of repeated, continuous contraction of the extensors of the wrists and fingers with the arm in pronation. The tenderness is more common over the whole course of the extensor group of muscles.

Diagnosis

The diagnosis is usually simple. The history of the injury is given often enough to establish the diagnosis. The kind of pain and the area of tenderness are characteristic. As I have said before, I am limiting my discussion to the acute or subacute so-called "*tennis elbow*" due to indirect trauma of specific activity requiring pronation and extension of the forearm, and the *occupational chronic epicondylitis*. Differential diagnosis must exclude the arthritides, such as chronic osteoarthritis and chondromatosis, rheumatoid, gonorrheal, luetic, tuberculous, gouty, or other types of arthritis. We must also exclude neuritis and neuralgia, such as occupational writer's cramp, toxic conditions, and infections from lead, nicotine, and alcohol, and also hypovitaminosis. X-rays are of little help. They are essentially negative. Only rarely do they show any periostitis, periostocortical tear, subperiosteal infraction, or Sudeck's bone atrophy.

Pathology

The anatomy reveals the muscles of the external epicondyle to wrist and fingers as quick-action muscles with short muscle bellies and long tendons. When too much tension is placed on these muscles, the tear occurs at their point of origin at the periosteum. The origin of the brachioradialis and extensor carpi radialis longus is almost proximal to the epicondyle, and the extensor carpi ulnaris lies deep to the extensor digitorum communis. The extensor carpi radialis brevis comes off most laterally on the condyle, and this is probably the muscle most often involved in the acute or subacute traumatic epicondylitis.

The pathology is probably a tear between the tendinous origin of the extensor carpi radialis brevis and the periosteum. A periostitis is produced, with more or less myofascitis and fibrositis in the muscle. A protective spasm is often found in the extensor muscles, which in turn will prevent complete extension of the elbow joint.

In occupational epicondylitis we probably deal with a chronic myositis of all the extensor muscles to wrist and fingers. A fibrositis may or may not be present. A study of the leverage of wrist extension and of the pronation of the forearm also favors the theory of a periostitis and a myofascitis.

Treatment

Immobilization.—In a previous article⁵ I analyzed 74 cases of epicondylitis treated by various forms of physical therapy in which the results were rather discouraging. In the 16 cases that were relieved by means of immobilization, the immobilization was accomplished by means of a cocked-up splint which shortened the extensor muscles from the lateral epicondyle and prevented full pronation. The physiologic rest thus gives the injured periosteum and muscles time to heal. Any myositis of the extensor muscles is treated with superficial and deep heat, followed by fairly vigorous massage. The patient should abstain from the game or occupation that was the causative agent. Immobilization is the treatment of choice in occupational epicondylitis.

Manipulation.—Since 1936 several articles on epicondylitis have been published in England and Australia. The interesting part of these papers was the high percentage of cures claimed to be achieved by a very simple manipulative treatment. Mills advocated a manipulation with the elbow in extension, the forearm pronated, and the wrist flexed. Cyriax, in a very comprehensive article, claimed nearly consistent cures with manipulation of the elbow in extension and the forearm in supination. The 67 cases I am reporting are not all mine, but they have been checked very carefully. A review of these *manipulated cases of epicondylitis* reveals the following figures:

Total cases manipulated	67
Female, 45 per cent; male, 55 per cent	
Manipulations per patient	1-14
Average age	43.7
Cases due to games	77 per cent
Cases due to occupation	23 per cent
Manipulated cases—cured	15 per cent
Manipulated cases—not improved	85 per cent

My conclusion is that manipulation probably has its place in the treatment of epicondylitis

of traumatic origin, if we employ it in the proper cases. It is my impression that patients presenting lack of complete extension in the elbow due to spasms of extensor muscles are the cases that should be manipulated until complete extension in the elbow is restored. Manipulations are rarely effective in the occupational type of epicondylitis.

Injection.—Injection of 0.5 cc. of 1 per cent procaine solution under the extensor tendon group, followed by 0.3 cc. of 5 per cent sodium morrhuate, has been recommended. However, any injection can give only temporary relief; therefore this procedure does not seem very rational.

Operation.—I have had no experience with cases in which operation was the treatment employed. The principle is to divide the tendon of origin of the extensor group of muscles where they come off the external epicondyle.

Conclusions

1. The pathology in traumatic epicondylitis is undoubtedly a partial rupture of fibrous origin of the extensor-supinator group of the forearm with periostitis and fibrositis. In occupational epicondylitis the pathology is probably more of a chronic myositis.

2. Manipulations may be attempted in traumatic cases in which extension is limited, owing to muscle spasm.

3. Immobilization is still the treatment of choice in most cases, with additional physical therapy for restoration of normal muscle tissue.

4. Injection of novocain gives only temporary relief, and operations are seldom indicated.

Discussion

Dr. I. D. Horwich, New York City—The divergent opinions concerning the nature of this lesion reflect themselves in the therapeutic proposals that have been made by various clinics. Suggested types of treatment include (1) cocked-up splintage, (2) manipulative maneuvers, and (3) operative procedures. One writer ventured a truth in a nutshell when he said that epicondylitis is a lesion which tends to heal with and without treatment.

At a symposium on tennis elbow given by the Royal Society of Medicine in 1929, the chairman, in closing a lengthy discussion, remarked that if time had permitted he would have liked to disagree with all of the previous speakers. (No doubt our chairman will be so inclined!) One editor remarked that the causes of tennis elbow are various; its pathology obscure; and its cure uncertain. Dr. Hansson has, I believe, clarified these matters to a great extent.

The diagnosis is simple and the symptoms are characteristic, yet this condition is often confused with other elbow pathologies. The most characteristic local finding is point tenderness. A sign that I consider pathognomonic is that the patient is unable to elevate a chair with the forearm pronated, but can lift a chair high off the floor with the supinated hand and forearm. When one considers the pathology as described by Dr. Hansson, this is quite understandable.

As regards the bursal theory embraced by Osgood and others, I believe that what is taken to be a bursa on operation is in reality an upward prolongation of the synovial sac of the elbow joint.

Considering manipulative maneuvers, Mills stresses the importance of an audible click as a criterion of a successful manipulation—forceable extension of the pronated forearm with the wrist flexed. Cyriax, arguing on theoretic grounds, believes that the position of physiologic rest on a cocked-up splint may predispose to recurrence of the condition by permitting healing to take place with shortening of the involved muscles. I do not know why this should be any more likely to occur in epicondylitis than in other deformities in which tenorrhaphy is utilized. Cyriax tries to convert a partial muscular tear into a complete one. After deep friction massage over the epicondyle, he extends and supinates the forearm and then sharply adducts the elbow into cubitus varus.

However, both Mills and Cyriax feel, as Dr. Hansson has said, that manipulation should be done only in those patients who show a slight springy resistance to full extension of the elbow.

In occasional protracted cases, I have used weekly manipulation as an adjunct to the immobilization treatment with a cocked-up splint. This did not appear to speed up the recovery.

Dr. Henry B. Crawford, Rochester, New York—I consider it a privilege to discuss this interesting and well-presented paper. Dr. Hansson's phylogenetic theory for the vulnerability of the extensor and abductor tendons is particularly appealing.

In attempting to criticize constructively this well-presented logic as to the pathology and treatment of the commonly called "tennis elbow," there is only one question that comes to my mind, and that is: Should we try to differentiate between (1) a subperiosteal fracture, (2) a calcareous degeneration of the tendons, similar to that which we commonly find in the

supraspinatus tendon, and (3) a radiohumeral bursitis?

This question has more than arm-chair theorizing for its basis. In reviewing the last 20 cases (see Table 1) diagnosed as "radiohumeral bursitis" in our office, I was surprised to find abnormal calcification in 9. Still more surprising to me was the direct correlation between the finding of calcification in direct contact with the epicondyle and a history of onset of pain immediately following a bruise on the epicondyle at least a month prior to the x-ray examination. There were 7 such histories, of which I have films. They all show this type of calcification.

There were 2 that showed diffuse calcareous deposits in the tendon. These did not give a definite history of onset of pain following injury, and one of these had complete, immediate, and lasting relief from aspiration. The other had no treatment in our office.

Those patients who showed no changes in x-ray gave histories of direct bumps within twelve days prior to examination, or onset with muscular strain such as that experienced in ironing, playing squash or bat ball, sawing wood, etc.

I would agree that splinting the wrist in the cocked-up position and immobilizing the elbow to prevent further irritation would be indicated in all three of these pathologic entities.

However, if such a differential diagnosis could be made, it would seem to me that we might expect splinting alone to be the preferable treatment for the epicondylar fracture. We might

TABLE 1.—TWENTY CASES OF "RADIOHUMERAL BURSITIS"

Patient	Injury	Time Elapsed Between Injury and X-ray	X-ray
McCann	Struck elbow	12 days	Negative
Holst	Bump	6 days	Negative
Bilger	Sawing wood	5 weeks	Negative
Calkins	Playing batball	4 weeks	Negative
Cohen	Bruise (?)	2 months	Negative
Braverman	None	3 months	Negative
Stevenson	None	5 weeks	Negative
Yackel	Twist	1 day	Negative
Hills	Squash	10 weeks	Negative
Murphy	None	6 months	Negative
Meyer	None	2 days	Negative
Asnass	Bump	2 months	Calcification epicondyle
Schultz	Bump	1½ years	Calcification epicondyle
Peters	Bump	3 months	Calcification epicondyle
Zizzo	Bump	7 months	Calcification epicondyle
Weining	Bump	1 month	Calcification epicondyle
Bauer	None	4 months	Calcification epicondyle
Tosch	Fell on hands	4 days	Old epicondylar separation
Simpson	Bump (?)	3 weeks (?) (pain 4 days)	Calcification of tendon
Thompson	None	2 months	Calcification of tendon

expect heat and massage or aspiration of calcareous debris to be of some added value in speeding up the recovery in the cases of calcareous degeneration of the tendon, and we might consider exploration for a radiohumeral bursitis only in those few cases that did not respond to conservative treatment.

RHEUMATIC FEVER AND HEART DISEASE PROGRAM

An intensive educational program on rheumatic fever and heart disease has been launched by the Metropolitan Life Insurance Company, with the cooperation and advice of the American Heart Association, the Academy of Pediatrics, and the Crippled Children's Division of the U.S. Children's Bureau.

The purpose of this activity is twofold. Through popular literature, addresses, radio programs, news releases, and advertisements, the public will be acquainted with the newer knowledge of rheumatic fever and rheumatic heart disease and their special wartime significance in overcrowded and insanitary environments. The program will stress the importance of early diagnosis, proper care for rheumatic fever victims, and the declining mortality rate among children in the younger age groups. The Metropolitan is using the services of its Field Staff in some three thousand communities, and it expects to reach over one million homes.

An equally important objective of this program will be to distribute to the medical profession up-to-date literature covering various aspects of the rheumatic fever problem. The printed ma-

terials for physicians will include a clinical booklet which sets forth in concise form the modern concept of the disease, criteria for its early diagnosis and treatment, methods of managing the disease and recognizing its cardiac involvements. This booklet is being developed in collaboration with special committees of the American Heart Association and the Academy of Pediatrics. The membership of these committees includes: Drs. T. Duckett Jones and Edward F. Bland, of Boston; Arthur C. DeGraff, Ann G. Kuttner, Homer Swift, and A. T. Martin, of New York City; Ethel C. Dunham and O. F. Hedley, of Washington, D.C.; Hugh McCulloch, of St. Louis; and Stanley Gibson, of Chicago. Others being consulted include Dr. May G. Wilson, of New York City; Dr. Albert Kaiser, of Rochester; Dr. David Rutstein, of Albany; and Dr. Elizabeth Huse, of Washington, D.C.

This program marks the first time that a national educational campaign has been undertaken to reach the general public and the medical profession with rheumatic fever literature, especially prepared according to the needs and interests of each group.

SPINAL FLUID EXAMINATIONS

Report of Investigation of Procedures Followed Throughout the United States

W. BAYARD LONG, M.D., and JACOB A. GOLDBERG, Ph.D., New York City

THE Association of Syphilis Clinics,* under the chairmanship of Dr. Howard Fox, has been interested in the routine procedures that are followed in making spinal punctures on patients attending syphilis clinics in New York City. For some years there has been distinct variation in methods used in hospitals and unaffiliated dispensaries which operate syphilis clinics. In certain clinics, where hospitalization has been the routine procedure, there often has resulted a backlog of several hundred patients awaiting their turn for admission to the one or two beds assigned for this purpose. This has brought about the failure of many syphilis patients to be given the benefit of a spinal fluid examination or, at least, considerable delay in carrying out this requisite step. Studies made in syphilis clinics of several thousand charts emphasized this lapse.

Every syphilologist agrees that it is important to examine the spinal fluid of a patient with syphilis. If it becomes necessary to hospitalize the patients for even twenty-four hours in order to perform a spinal puncture, the number of such punctures will be enormously reduced. This has been found to be the case for two specific reasons: (1) the lack of adequate hospital beds for this purpose; (2) many patients who would submit to spinal puncture in the dispensary are unwilling or unable to spend the night in the hospital for that purpose. It is generally assumed that after the spinal puncture it is advisable for the patient to rest at least one-half hour and then go home without delay. Some physicians prefer to have the patient rest for two or three hours. While it is true that a patient may faint in the street after a spinal puncture, this may also occur after an injection of arsphenamine or numerous other medical or surgical procedures. Although an occasional patient becomes sick on the way home following a spinal puncture, it is not sufficient reason to make a hard and fast rule that all such patients must be hospitalized. The question of doing the most good to the vast majority of persons with syphilis outweighs any incon-

venience that may be suffered by a small minority. The members of the Association of Syphilis Clinics have expressed the opinion that the performance of spinal punctures on ambulatory patients is a safe procedure. This decision was particularly emphasized at a meeting of the Association of Syphilis Clinics held on May 26, 1939. At this meeting the Association passed a resolution to the effect that "The Association of Syphilis Clinics goes on record as agreed that lumbar punctures should be routine in clinics." This motion was carried unanimously. Subsequent to this meeting the words of this resolution were sent to all directors and superintendents of hospitals and dispensaries in the city in which syphilis is treated. Within a short time favorable results followed the receipt of this letter, some hospitals instituting the procedure recommended in the resolution. However, hospitalization is still the routine procedure in certain institutions.

In the attempt to learn what was common procedure throughout the country, an inquiry was sent to the venereal disease control medical officers of all the state departments of health and to the health commissioner of the District of Columbia. Reports from the departments of health of the various states have been received, and they are included in the following pages. It will be noted from the tabulation that, with few exceptions, spinal punctures are routine in the clinics.

It is hoped that further evidence of common practice in New York City and throughout the country may induce those who are still insistent upon hospitalization to modify their procedures and make it possible for larger numbers of syphilis patients to be given spinal fluid examinations. Even if adequate hospital facilities are available, it is not deemed desirable to involve the patient in unnecessary expense, or to put the hospital to the expense of hospitalizing indigent or quasi-indigent patients or those for whose hospitalization full costs cannot be provided.

Summary

It is generally recognized that it is necessary to make spinal fluid examinations during

Chairman and Secretary, respectively, Social Hygiene Committee, New York Tuberculosis and Health Association.

* Affiliated with Social Hygiene Committee, New York Tuberculosis and Health Association.

SPINAL FLUID EXAMINATIONS

State	In Clinic	In Hospital	Rest Period	Remarks
Alabama	X	—	At least 2 hours	Advised to rest 24 hours
Arizona	X	—	—	—
Arkansas	X	—	None	On all early cases following completion of second course of arsenical therapy
California	X	—	None	On all early latent, late latent, and late cases before treatment is started, check all early cases at end of six months
Colorado	X	—	Half hour	Beds as available but never used
Connecticut	X	—	—	State Department of Health encourages spinal punctures in clinics
Delaware	X	—	None	Advised to go home and go to bed
Dist of Col	X	—	None	Rest in bed for 24 hours
Florida	X	X	—	Discretionary
Georgia	X	X	Few hours	Only in some clinics affiliations hospitalize patients for a few hours, very few stay overnight
Idaho	X	—	—	Nearly all patients examined
Illinois	X	X	—	Clinics equipped for spinal punctures, some physicians prefer to hospitalize patients for one day
Indiana	X	X	Few hours	Both plans followed, clinic plan recommended with short rest period, except in special cases
Iowa	X	—	—	Routine procedure, few reactions, none hospitalized
Kansas	X	X	One hour	Most clinic physicians insist on hospitalization, one large clinic does cisternal punctures on every patient in clinic
Kentucky	X	—	—	In 130 clinics spinal punctures are done in clinic
Louisiana	X	—	None	Rest in bed at home for 24 hours advised
Maine	X	X	—	Recommend spinal punctures in clinics, many "clinic" patients treated in physicians' private offices who prefer hospitalization
Maryland	X	X	—	As a general rule in hospitals some clinicians have developed technic and do spinal punctures in clinics
Massachusetts	X	X	Varies	Recommend spinal punctures in clinic and patient to be sent home immediately, some keep patient overnight
Michigan	X	—	—	About one-half of the patients get at least one spinal puncture during course of treatment
Minnesota	X	X	Varies	Increasing tendency to do spinal punctures in clinics
Mississippi	X	—	Varies	Spinal punctures in 200 clinics, no hospitalization
Missouri	X	X	—	Recommend spinal punctures in clinics, number of patients hospitalized
Montana	—	X	—	Hospitalization routine
Nebraska	X	—	—	Spinal puncture during first six months of treatment.
Nevada	X	—	—	Only one clinic in Reno; another planned.
New Hampshire	—	X	—	Hospitalization routine.
New Jersey	X	X	Two hours	Recommend spinal punctures in clinics, hospitalization still common where cisternals are done in clinic, highest percentage of patients obtain spinal puncture before discharge
New Mexico	X	—	—	No provision made for hospitalization.
New York	X	X	Varies	In New York City spinal punctures largely done in clinics, with tendency to change from hospitalization requirement State Department of Health for some years has urged lumbar punctures be made in clinic in smaller communities general practice is to hospitalize patients, with growing tendency toward clinic plan
North Carolina	X	—	None	Recommend rest at home for 48 hours
North Dakota	X	—	1 to 2 hours	Only one syphilis clinic in state, rest on abdomen in clinic for one to two hours
Ohio	X	X	—	Recommend spinal punctures in clinic, clinics in larger cities usually follow this plan, in small communities there is a tendency to hospitalization because of lack of well-trained personnel
Oklahoma	X	—	—	In 66 state-sponsored clinics spinal punctures in clinic, only few reactions
Oregon	X	—	—	State Board of Health recommends spinal punctures as outpatient procedure
Pennsylvania	X	X	—	Large institutions usually make spinal punctures in clinic, rest for two hours in some
Rhode Island	X	X	—	Majority of clinics make spinal punctures in clinic, very few patients hospitalized
South Carolina	X	X	—	In clinics located in cities both plans followed, spinal punctures found impractical in rural areas
South Dakota	X	?	—	No clinics, all treatment in private offices of physicians, number of physicians make spinal punctures in offices, data on hospitalization not available
Tennessee	X	X	—	In majority of communities patient is not hospitalized
Texas	X	—	None	Recommend spinal punctures to be made in clinic, patients advised to go home and lie down
Utah	X	—	—	Spinal punctures routine after six months of treatment, repeated every six months
Vermont	—	X	—	Usual custom to hospitalize proper facilities not available in state outside of hospitals
Virginia	X	—	—	Recommend spinal punctures be made in clinic on early cases at end of six months of treatment
Washington	X	—	None	Patient sent home at once, recommend at least 24 hours in bed
West Virginia	X	—	None	Patient sent home at once, instructed to remain in bed remainder of day, and following day if headache develops.
Wisconsin	X	X	—	About 95 per cent of patients hospitalized
Wyoming	X	X	—	Plan left to judgment of clinic directors, many spinal punctures made in clinic with considerable success

the course of treatment for syphilis. The older and more conservative method, first applied when salvarsan came into use, was to make of this technic a hospital procedure. The data presented in the preceding pages definitely indicate that it is more or less a general plan throughout the country to make spinal punctures in clinics, allowing for a period of rest. When hospitalization is required, as has been found in some clinics, many of the patients are not given the benefit of a spinal fluid examination or, if such is given, it is only after considerable delay.

Another factor that must be taken into consideration is that particularly for patients attending public clinics, whose income or available funds are limited, the cost to the

patient for overnight stay in a hospital may be much beyond his or her means. Where the hospitals provide the beds free of charge, the cost to the hospital must be taken into consideration. Patients who are required to stay out for twelve or twenty-four hours, which is the usual routine, are often in danger of losing their jobs, or certainly of losing a day's pay.

It is hoped that this memorandum may be of some help in convincing medical boards, hospital administrators, and staff members of the desirability of following the plan now generally followed in New York City and even to a greater extent throughout the country—and that is to make spinal punctures in the clinic, allowing for necessary periods of rest thereafter if deemed desirable.

Prize Essay

THE Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, May 3, 1943, in Buffalo, New York. This prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The following conditions must be observed:

Essays shall be typewritten or printed, with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win the prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than March 1, 1943, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York City.

CHAS. GORDON HEYD, M.D., *Chairman*
Committee on Prize Essays

SURGERY IN THE AGED

FREDERICK W. BANCROFT, M.D., New York City

IN ATTEMPTING to discuss surgery of the aged one must first define the term "aged," and this depends somewhat on the age of the observer. I can remember well, during the first World War, thinking that the medical consultants of the A.E.F. were old men, but a recent study of their ages shows that almost all were under 55 years. At present this age seems young to me.

Labor considers 40 as old age. For the purpose of this paper, I shall consider from 65 years onward as the aged, recognizing, nevertheless, that we have all seen patients of 50 years who were much older in their arteries, their outlook on life, and their minds than others who were over 70.

Isidore Cohn presents one of the latter old-young group as follows: "A letter written by a lady to her pastor expresses very well the difference between the aging process and chronology. She states: 'This is an old lady writing to you. At least, the house she lives in is 82. Considering its age the house is in thoroughly good repair, though I don't think it looks quite as well as it did 50 years ago. I have neglected to keep it painted, as so many women of this generation do. To tell the truth, I have been spending my time on interior decorations. The windows I look out of are fairly clear, and I am glad to tell you I have a reliable tenant in the upper story.' This is a familiar experience to the surgeon. It is the condition of the patient, rather than the age, which is the determining factor in operative mortality in the aged."

The problem of geriatrics is an ever-enlarging one. More people live in the cancer, diabetic, cardiorespiratory and arteriosclerotic period than ever before, and this army will increase unless the present World War changes the living conditions in America.

We now have 6,500,000 people of 65 years or over, and, if the present figures of longevity continue on their normal upcourse, by 1980 it has been estimated that we will have 25,000,000 of this age alive.

Statistics indicate that the life expectancy in the United States has changed considerably in the last century. In 1850 the life expectancy of white males was about 39 years. By 1930 the average duration of life had increased

to 59 years. In 1850 the total population of the United States was about 23,000,000. Of this number, less than 1,500,000 reached the period between 50 and 64, and only six-tenths of a million were over 65 years of age. In 1930, of a total population of 123,000,000, 14,000,000 reached the ages of 50 to 64, and 6,600,000 were 65 and over.

In other words, in 1850 the population between 50 and 64 years of age was 6 per cent. In 1900 this had increased to 9 per cent, and by 1930 the average of the population between 50 and 64 years of age had reached 11 per cent. Thus, the increase in population over 65 had advanced, between 1850 and 1930, from 2 per cent to 5 per cent.

With this increased number of patients reaching the aged group, the knowledge of biochemistry, the improvement in anesthesia, and the delicate touch of the surgeon have made it possible for surgeons not only to keep up with the parade, but to enlarge safely the scope of surgical treatment.

Before entering upon a detailed discussion of surgical procedures it is advisable to lay down certain principles that may guide our general course.

The following indications for surgery for this age group will be accepted, I believe, by the majority of surgeons. These are operations devised for:

1. The relief of pain.
2. Relief of infection, if the operative procedure is not too hazardous.
3. Mobilization of a patient out of bed, because the dangers of being bedridden are greater than the operative risk. The main example of this type of surgery is in the internal fixation of fractures of the neck of the femur in order to get the patient up.
4. Excision of cancer.
5. Relief of gangrene in peripheral vascular diseases.
6. Relief of chronic obstructive diseases, as the hypertrophied prostate, pyloric obstruction, etc.

While the above are general principles that may be followed, there are exceptions to most of them. The following is an example of such an exception. A frail old man of 84 years of age was admitted to the City Hospital of New York with obstruction of the colon due to

malignancy. Operation would necessitate certainly a colostomy, and possibly a second-stage resection. The problem was presented to the patient that operation would necessitate the draining of the bowel on the abdomen, with considerable risk from this operation, and a later procedure of greater magnitude would be necessary should he survive the first operation and desire to have the fecal current re-established. He stated frankly that he had lived his life and did not desire surgery. He died about four days later, but had been given morphine enough to have a comfortable exodus.

Other exceptions are those of frail old people with gangrene of the extremities. It is obvious to the surgeon that such a patient will never be able to navigate either by crutches or artificial leg. I believe that such a patient should have the problem presented to him of both extremes—the one of surgery and the one without surgery—and be allowed to make a decision. One difficulty encountered in this type of patient is that the children desire to make the decision for their parents. If the patient is conscious, it is his or her sole right to decide which procedure should be carried out. It is true that the children may influence the parent's decision, but the parent, in the end, is alone responsible.

If operations are considered in the aged, whether they be emergency or elective procedures, preoperative knowledge of the patients' blood chemistry is much more important than in the more active years of life. Traumatic accidents are fewer in this group because of their more sedentary type of life, and infection travels less rapidly because of the fibrous degeneration of the tissues. As an example, acute appendicitis occurs occasionally in an elderly person. It may develop with very few signs and not be recognized until an abscess has been formed. The risk of diffuse peritonitis is less than in the younger age. In such conditions the drainage of the abscess is a simple procedure. It is only when the vascular supply of a part is interfered with, as in gangrene or strangulated hernia, that we must make haste in operating.

If we have time, and we usually do, to prepare a patient for operation, what preoperative laboratory work is advisable, and what preoperative preparation should be instituted?

Before attempting the laboratory studies, Boyd makes the following observations: "Careful study of the patient, his gait, his acumen of hearing, of seeing, or motion, his posture, his cold or warm hands and feet,

his very outlook on life—all mean volumes if we can interpret them. The build of the patient, his present weight, condition of the skin, his intellectual apprehension of situations, his perspective, his ability to absorb external impressions with poise, his very facial expressions—all are great aids to the observing doctor. A tortuous, bulging, bounding temporal artery, moist or dry skin, a shaking hand, a quavering voice, a markedly underweight, or overweight condition, a lack of confidence or a superabundance of confidence, all spell either success or disaster."

The following factors should be considered in examining the patient: (1) an estimate of the cardiac reserve. Can a patient walk around the block with ease, or can he climb a flight of stairs without too much exhaustion? (2) An estimate of his ability to take an anesthetic, and a careful study of the type of anesthesia for the patient's age and surgical condition.

The genitourinary system should be carefully analyzed. In elderly men one must consider, if an operation on the extraordinary tract is contemplated, whether the anesthesia or bed rest, or the operative trauma, may create the remaining edema of the prostate which may become an immediate postoperative problem. These patients should have routine blood chemistry examinations, including study of the urea nitrogen, nonprotein nitrogen, and plasma protein determinations. The plasma protein is often low in the aged because of their altered eating habits due to changes in dentures. The protein content may be surprisingly low, and we may be able to avoid eventrations of the abdominal wound, rupture of the suture line if intestinal anastomoses are made, by correcting the hypoproteinemia by either increasing the protein intake by mouth or, if this is impossible, by either blood or plasma transfusions.

A careful study of the vitamin intake of the patient before admission may also save us from similar pitfalls. Nicotinic acid, 50 mg. three times a day, may change a bewildered elderly person into a satisfactory surgical risk.

Anesthesia.—With all of the improved anesthetic agents at our disposal, the problem of anesthesia in geriatrics probably requires more surgical judgment than the operative procedure itself. In abdominal cases the use of novocain, local and block anesthesia, supplemented by either gas or intravenous anesthesia, is probably, in the majority of cases, the safest procedure. Spinal anesthesia in many cases works like a charm, but where

there is hypertension with a high diastolic pressure, the pulse pressure may be so diminished that it is difficult to restore it—even by heroic means. Cyclopropane, often supplemented with a minimum dose of avertin, will in many cases prove the anesthesia of choice.

In surgery of the extremities a new anesthetic principle has recently come into prominence which may save many lives and solve a difficult problem. Cryotherapy—that is, the application of cold—to an extremity, has proved to be a very useful adjunct in peripheral vascular diseases. If a tourniquet is applied, and the leg packed in ice for two hours preceding a lower thigh amputation, or one and a half hours preceding a lower leg amputation, it has been shown by Crossman, Ruggiero, and Allen that amputation may be performed with very little anesthetic risk. The patient has practically no shock and can return to a normal diet immediately after the operation. In these cases it is advisable to keep ice on the extremity for two or three days postoperatively, in order to keep the metabolism at a low enough rate so that the diminished circulation may supply sufficient nourishment.

Gentleness of handling tissues in the aged is most important. Their vessels are sclerotic, and their tissues often friable. In abdominal procedures the mesentery tears easily, and unnecessary time may be used in attempting to get bleeders in the omentum or mesocolon which have been caused by rough handling. Utmost delicacy of touch must be used. The sulfonamide drugs, both local and parenteral, are of great aid in the treatment of infections, but one must remember that the aged are more apt to develop late deficiency diseases through prolonged use of the sulfonamide remedies, and therefore they should be discontinued as soon as possible.

Treatment.—During the operative procedure it is advisable, if the procedure is to last for any length of time, to administer either blood, plasma, or glucose intravenously in order to prevent the insidious onset of shock. As the myocardium is not so adaptable to increased blood pressures, one must be careful to give the intravenous solutions slowly in order not to embarrass the right heart.

Adrenal cortex extract given before and after operation is often advisable. Operative procedures should be based on the minimum surgery that will give the patient relief. Life expectancy of a 75-year-old patient is not very long. In cancer surgery one must be sure

to give the patient sufficient relief to justify the procedure. Burton Lee has shown that cancer of the breast in elderly women who have a long history of a lump is a relatively benign disease as compared with the same condition in a younger individual. Usually in many of these elderly people the excision of the breast itself, without axillary dissection, will give them a life expectancy as long as one would naturally expect. I have recently heard from a woman of 80 who had a large carcinoma of the breast and would not have been able to withstand a radical resection. I removed her breast three years ago and at the present time she is in fairly good health.

Cancer of the gastrointestinal organs presents a more difficult problem. One wonders whether palliative operations for gastric or intestinal lesions are sometimes justified. I have performed gastroenterostomy for pyloric obstruction due to cancer and wondered whether the hospitalization and the suffering were worth the short period of time the patient was given relief. Two or three times I have attempted a jejunostomy on an inoperable carcinoma of the stomach with obstruction and have been disappointed with the results. The cramps resulting from tube feeding and the inability of the old tissues to absorb nourishment given through a jejunostomy tube have made me feel that this procedure is not warranted. If I were in the late seventies and had a carcinoma of the stomach which was irremovable, I am sure I would prefer morphinism to any palliative procedure. On the other hand, if the carcinoma of the stomach is nonremovable but can be excluded from the cardia by either suture or the use of the von Petz clamp, and a gastrojejunostomy can be made between the cardia and the jejunum, relief may be given the patient for a considerable period of time. By this procedure the sloughing, carcinomatous mass in the prepyloric area of the stomach is excluded from the mixture of food, and the patient may enjoy the intake of food, and have a relatively long period of happiness. This procedure, I think, is justifiable.

In obstructive lesions of the lower bowel one must, I believe, analyze the patient's age, the amount of life expectancy that one can give by relief, and then, perhaps, in a humane manner, present the problem to the patient for his own decision.

Postoperative Treatment.—Hyperventilation of the lungs with oxygen and carbon dioxide is often a procedure of considerable advantage. Elderly patients must be kept

moving in order not to develop a hypostatic pneumonia, and they should be got out of bed at the earliest possible moment. If their condition permits, feeding should be done as soon after operation as possible. No matter how we give nourishment, there is no substitute for food by mouth.

Alvarez has shown that the discharge of food from the pylorus into the duodenum produces a peristaltic wave throughout the intestines. Distention is caused largely by air swallowing, but lack of food is also a prominent factor, because if there is stasis bacteria multiply and fermentation occurs and gas is created; therefore, food given early, and the early evacuation of the lower bowel, deters distention.

It is important that the abdominal dressings be loosely applied, because distention, with a tight abdominal dressing compressing the intestines, not only favors obstruction but also slows the blood stream through the vena cava. We all know that venous stasis is one of the main factors creating thrombosis and embolism. Therefore, our efforts should be directed toward preventing distention, active motion of the legs, often against resistance as described by Pool, and copious use of fluids as a prophylactic measure. If a patient runs an unexplained low elevation of temperature postoperatively for more than four or five days, it has been my practice to administer sodium

thiosulfate as a prophylaxis against thrombosis. After a study of many hundreds of cases I am convinced that this measure does not do any harm but does do a great deal of good. It has been my good fortune never to have had an embolus develop in a patient who had had sodium thiosulfate given prophylactically.

It might be assumed from the foregoing that the writer is opposed to radical surgery in the old-age group. This is far from the case. I am thoroughly in favor of subtotal gastrectomies, colectomies, abdominoperineal resections and radical mastectomies, or other surgical procedures where operation offers the patient a reasonable life expectancy and where the patient is in good condition and can be hospitalized in an institution where he can have proper preoperative therapy and where satisfactory care can be given in the event of a postoperative emergency.

Conclusions

Surgery of the aged, with modern public health precautions, will have an ever-increasing scope. Careful preoperative preparation, wise consideration in the choice of an anesthetic, a careful nontraumatic approach, and, finally, well-advised postoperative measures will diminish the mortality and morbidity in this group.

DR. FISHBEIN'S STORK CLUB

There are confirmed collectors of everything from collar buttons to auk eggs, but Dr. Morris Fishbein, of Chicago, spokesman for the American Medical Association and editor of the *J.A.M.A.*, is probably the world's only collector of odd and amusing birth announcements. Parents who send out "stork calling cards" usually include their obstetricians, who, in turn, forward their favorites to Dr. Fishbein. Today, his collection numbers more than 1,000! He thinks the best ones are the boners, like this one which appeared in a Winnipeg newspaper: "BROWN: Born to Mr. and Mrs. S. G. Brown, of Dublin, Ireland, formerly of Winnipeg, on June 28, a son, by special cable." Among other wacky announcements in the collection are a special diaper ration book, a one-page newspaper greeting the new arrival with headlines, and a dinner menu.

One of America's busiest doctors, St. Louis-born Fishbein has never practiced on his own.

But he manages to write a book a year, serves on seventeen medical and research committees, acts as associate professor of clinical medicine at the University of Chicago, delivers ten speeches a month, goes over thirty-five medical manuscripts a day. To maintain his pace, he sleeps only six hours a night, talks fast (200 to 320 words a minute), and reads so rapidly he breezes through *Gone With the Wind* in less than five hours (average—four pages a minute). He enjoys exotic foods in moderation and limits his drinks to two a day. He plays good golf (handicap twelve) and expert bridge (he often gives handicaps to his opponents). His personal prescription for relaxation is writing 15,000 words weekly in his diary, which chronicles the activities of a modern "Dr. Pepys." Strange as it seems, neither Dr. nor Mrs. Fishbein, when their two sons and two daughters were born, remembered to send out stork cards themselves.—*J. Med. Soc. of Cape May County, N.J.*

AN OUTBREAK OF ACUTE FLUORIDE POISONING

H. S. INGRAHAM, M.D., Kingston, New York, and
A. J. FLOOD, M.D., Coxsackie, New York

ONE of the earliest reports on the poisonous qualities of fluorine salts originated in this country in 1899, with a paper in the *Journal of the American Chemical Society*, by Baldwin.¹ Since that date, isolated instances of poisoning, both fatal and nonfatal, have been described. These reports have usually concerned individuals or families. The following one is presented because of the considerable number of persons involved and because it illustrates once again the danger of having fluorine salts available in cooking establishments.

On December 26, 1939, our attention was called to the sudden occurrence of numerous cases of gastroenteric illness among inmates of a New York State reform school. The institution at the time was comprised of 631 male inmates, aged 16 to 22, the staff consisting of 150 persons. On investigation, it was found that 69 persons had been affected in the course of two and one-half hours after the noon meal of that day. All were inmates and all were among the group who had eaten at an early serving of the noon meal.

The symptoms varied in severity, but a typical patient experienced a very sudden onset of nausea, followed immediately by repeated vomiting, with severe cramplike pain in the epigastrium, and later by one or two loose bowel movements. Weakness and sweating were prominent symptoms. Headache, salivation, and lacrimation were present, although none of them in extreme degree. The frequency of vomiting varied from one to fifteen times, with a tendency for repeated retching to occur after the stomach had become empty. A very few patients failed to vomit, complaining only of nausea. None developed a true diarrhea, and nearly half the patients had no bowel evacuation during the course of the illness. There was no blood seen in the vomitus and neither blood nor mucus in the bowel discharge. None of the patients was febrile. Although weakness was complained of in all cases, in none was it carried to

the point of complete and persistent prostration. The severity of the symptoms was attested to by the fact that many patients were highly apprehensive and fearful of impending dissolution. Recovery was remarkably prompt, and except for residual weakness most patients had recovered in about three hours after onset and by the next morning all were completely well, except that anorexia and vague epigastric uneasiness and soreness were complained of rather generally for several days.

Since the nature of the inciting agent was not known at the time, it was not possible to institute any specific therapy. As it was apparent that some irritative agent had been ingested, some of the early patients were given syrup of ipecac, but since it became quickly obvious that evacuation of stomach contents was proceeding spontaneously, this was discontinued.

The period of incubation, if one might call it that, was short. Several patients vomited before they were able to rise from the table. A number more did not reach their quarters before they were overcome, and most were seized within ten minutes of finishing their dessert. In only one instance was the time between lunch and illness greater than a half hour, one patient reporting that he had not been affected until two and one-half hours after eating.

There was no doubt that some article of food ingested at the noon meal was responsible for the syndrome. In this instance, circumstances were such that it was possible to determine the offending food with complete accuracy and assurance. The noon meal consisted of frankfurters, sauerkraut, gravy, bread, potatoes, and cocoa, with chocolate pudding served for dessert. Each of these foods had been prepared as a single lot in the morning preceding the meal. Some of the inmates, however, were served shortly before noon. This group, a total of 143, was made up of workers in the kitchen, dining room, and bakery who ate in the regular dining room, and of those inmates confined to the hospital, to quarantine, or to the disciplinary division, each of the latter groups being served in their respective quarters. Cases were distributed with equal frequency among each of

District State Health Officer, New York State Department of Health, Kingston, New York, and Senior Physician, New York State Department of Correction, Coxsackie, New York, respectively.

these four groups, all having been attacked simultaneously shortly after completion of the meal.

As soon as it was learned that a considerable number of the boys were sick, the noon meal was blamed and several of the inmates volunteered the information that they believed the chocolate pudding was at fault, although they were unable to state definitely that the pudding tasted unusual. A quick survey by one of us tended to confirm this suspicion, and the remaining 488 inmates were served precisely the same foods from the same kettles, except that the chocolate pudding was omitted and canned loganberries were substituted as the dessert. Not a single one of the 488 became sick. A careful investigation revealed no other variations in the meal between the two servings aside from the difference of twenty to sixty minutes in serving time and the substitution of the canned loganberries for the chocolate pudding. These facts in themselves established beyond reasonable doubt that the chocolate pudding was the offending article, and for this reason a complete food history was not taken from each of the inmates. It was determined, however, that of the 143 inmates who ate at the first serving, 96 had eaten the chocolate pudding. The 69 cases of illness occurred among the 96 who gave a history of having eaten the pudding. There was no illness among the 47 inmates at the first serving who ate no pudding.

As a matter of routine investigation of a gastroenteritis outbreak, the water, food, and milk supplies were looked into, and the question of open sores or illness in the kitchen personnel was checked. Nothing of significance was thus elicited.

The chocolate pudding was mixed at 6:00 A.M. on December 26. It was made of 4 cans of a commercially prepared chocolate mixture, 3 pounds of cocoa powder, 2 forty-quart cans of milk, 12½ pounds of cornstarch, 20 quarts of water, and sugar to taste. This mixture was cooked with constant stirring, from fifteen to twenty-five minutes. Raisins and vanilla were added subsequent to cooking. The mixture was then poured into 27 cooling pans and left at room temperature for one hour. Another cook entered the kitchen at 7:30 A.M., scrutinized the pudding, pronounced it too thin, ordered the cooling pans to be emptied back into the heater, and then added a panful of flour. The mixture was again heated and cooked, then repoured into the same 27 cooling pans, and left at room temperature for one hour, after which it was

put in the refrigerator to cool before serving. The preparation of the chocolate pudding was under the general supervision of two employee cooks. The actual making of it, however, was entrusted entirely to 2 inmates. It was of interest that one of the inmates who prepared the mixture ate the pudding and became ill, while the other ate none of the pudding and did not become ill.

As stated previously, one of us had ordered the chocolate pudding withdrawn from circulation. However, this order had been anticipated and all but one of the cooling pans full of pudding had been poured down the sink as soon as cases of illness began to appear. There seemed to be a general knowledge among some of the kitchen personnel that the chocolate pudding was at fault. These circumstances, together with the extremely short incubation periods, made it appear almost certain that someone in the kitchen had deliberately added an obnoxious substance to the pudding and that we were dealing with chemical rather than bacterial poisoning. The only poisonous substance found anywhere on the premises was a large bag of sodium fluoride that was used as roach powder and kept in a corner of the kitchen at all times, along with a large blower containing about a pound of the powder. Three separate samples of the remaining pudding taken from different parts of the cooling pan were forwarded to the State Health Department Laboratory for examination for poisonous substances. One specimen was found to contain 0.1 of 1 per cent of sodium fluoride, another 0.2 of 1 per cent, and the other 0.3 of 1 per cent, apparently indicating that the substance had not been thoroughly mixed into the pudding. Since the average amount of pudding served weighed approximately 200 Gm., it would appear that those eating the full portion of pudding ingested roughly from 0.2 to 0.6 of 1 Gm., which is considerably less than the reported fatal dose of sodium fluoride.

Twenty-seven inmates who ate the pudding apparently experienced no symptoms at all. It is possible that some portions of the pudding contained even less than 0.1 of 1 per cent, making the total dose less than 0.2 of 1 Gm., which may be somewhat less than the average nauseating dose. *It is also possible that the presence of large amounts of milk in the pudding may have acted as a partial antidote to the effects of the fluoride.* The fact that symptoms did occur in so high a percentage of cases when the salt was administered in a vehicle consisting largely of milk tends to cast

some doubt on the efficacy of milk as an antidote. It must be admitted, however, that no clear conclusions can be drawn on this point, as certain parts of the pudding may have contained much larger percentages than those analyzed.

Two additional cases should be noted. The storeroom clerk expressed doubt that the chocolate pudding had caused difficulty and ate a small portion consisting of about 4 teaspoonfuls. Within a half hour he experienced a moderately severe nausea with mild epigastric pains but developed no other symptoms and quickly recovered. One of the employee cooks was apparently convinced that the pudding had caused difficulties but doubted greatly that the roach powder was the offending poison. As a practical test, he added approximately one-quarter teaspoonful of the roach powder to a glass of water and then drank between one-quarter and one-third of the mixture. Within twenty minutes, he was seized by a violent nausea and epigastric pain, accompanied by salivation, lacrimation, headache, and weakness. He immediately reported for treatment and was given a large dose of ipecac, following which he vomited repeatedly and recovered promptly.

One of the inmate cooks, as he was later being paroled, admitted privately to one of us that he had scooped up as much roach powder as he could hold in one hand and cast it into the pudding. He was hazy as to when in the process the salt was added. His purpose, as stated, was "to get even" with another inmate.

A review of the literature reveals that the two most commonly used fluorine salts are sodium fluoride and sodium fluosilicate. Both salts are popular as roach powders. Sodium fluosilicate, weight for weight, is considerably more toxic than sodium fluoride, the difference being due to the relatively greater fluorine content of the former chemical.²

The toxicity of fluorine compounds is believed to lie chiefly in the ability of the fluoride ion to precipitate calcium and produce calcium deprivation, although it is certain that there are other important direct toxic effects.

Symptoms of fluoride poisoning generally follow within a few minutes after the chemical is swallowed and consist of nausea, epigastric pain, violent vomiting, and weakness, with headache, salivation, lacrimation, and sweating, followed shortly by diarrhea. In severe cases the vomitus is usually bloody and there may be cyanosis of the skin and

mucous membranes. Purpuric spots may appear on the skin. Death is usually preceded by convulsions and may occur within an hour or be delayed as long as twenty hours. A number of cases have been reported in which, following several hours of treatment, the patient appeared to be well on the way to recovery, and then suddenly died.

It is difficult to estimate the minimum lethal dose of sodium fluoride because of its tendency to cause repeated vomiting, but it is believed to be about 3 Gm., the lethal dose of sodium fluosilicate being considerably less.

Postmortem findings include premature rigor mortis, hemorrhagic gastritis, petechial hemorrhages of the skin, and continued oozing of blood from cut surfaces of muscles. Degenerative changes in the liver and kidneys have also been reported, as well as hemorrhages into the lungs.

It is generally conceded that soluble calcium compounds are the best antidote for fluoride poisoning. Calcium has a twofold effect, as it precipitates soluble fluoride salts as the relatively insoluble calcium fluoride, and supplies calcium to replace that already removed from the body. Calcium salts or calcium hydroxide should be given by lavage, and repeated infusions of soluble calcium salt should be given by vein.

In our own case, it was not possible to determine the probable nature of the poison until the patients appeared to be recovering. Hence, no attempt at specific therapy was made. In view of the reports of sudden death occurring several hours after apparent symptomatic recovery, it would appear that strenuous treatment should be instituted for every case in which fluoride poisoning is suspected.

The fluorine salts have been mistaken for a wide variety of substances and added to foods unwittingly. Some of these are sodium bicarbonate,³ powdered sugar,⁴ cornstarch,⁵ and baking powder.⁶ The salts have also been mistaken for various saline laxatives,^{5,6,7,8} on a number of occasions. In the particular instance reviewed here, the substance was added to foodstuffs deliberately, but it does illustrate the undesirability of having fluorine salts available in cooking establishments, particularly where irresponsible persons have access to both the poison and the foods.

A law has been enacted in several states requiring that colored pigments be added to the fluorine salts before they are sold. It would appear that this law is worthy of being generally copied.⁹

Summary

An outbreak of fluoride poisoning involving 71 nonfatal cases is described, in which the illness was caused by the deliberate addition of sodium fluoride to chocolate pudding. The outbreak calls attention to the fact that explosive outbreaks of afebrile gastroenteritis may be caused by chemical poisons rather than by the more commonly encountered staphylococcal toxin. It also directs attention to the danger of permitting access by irresponsible persons or children to fluoride or fluosilicate salts, or of having the salts avail-

able where they may be mistaken for food-stuffs or laxatives.

TROPIC DISEASE MENACE SPREAD BY AIR TRAVEL

Largely as a result of the expansion in air travel, the parasitic diseases of the tropics, including malaria and sleeping sickness, have become a potential menace to the health of inhabitants of other sections of the globe, according to Dr. James T. Culbertson, a member of the department of bacteriology of the School of Medicine of Columbia University.

Dr. Culbertson discussed the universal threat presented by the ancient scourges of mankind in a handbook entitled "Medical Parasitology" that has just been published by the Columbia University Press. Fortunately, Dr. Culbertson noted, specific drugs which lead to the cure of most of the infections are known to medical science. In time, he predicted, vaccination may render men relatively resistant to the organisms and possibly absolutely immune to infection. Disease-bearing parasites are a particular menace to the United States members of armed forces stationed in tropical and semitropical areas, Dr. Culbertson stated.

"All the parasitic infections now seem likely to experience a new and widespread distribution to fresh areas as a consequence of the rise in business and travel which, in large part, air transport has made possible," Dr. Culbertson writes. "Workers or travelers returning by airplane from

areas long notorious as disease centers may not reveal symptoms of the infections they have contracted until after they have reached home. The chance of the spread of the disease to their relatives and other associates at home is thus enhanced.

"An added hazard is the transportation, unnoticed, aboard long-distance planes of infected flies, mosquitos, fleas, or other disease vectors which remain entirely capable of transmitting the diseases in the regions to which they are carried.

"Thus far, the most significant results of the application of principles of immunity to the parasitic infections of man have been in the diagnosis of disease," Dr. Culbertson continued. . . . "As yet, with no parasitic infection has the vaccination of man been tried significantly."

"The greatest hope of protection against these dread maladies will come through a more adequate diffusion of knowledge of the agents which cause them," Dr. Culbertson asserted, adding that up to now the nation's medical schools have offered "comparatively little instruction" in the study of the causes of the parasitic diseases. Education for the layman as well as the physician is "probably in the end the most effective method of prophylaxis," Dr. Culbertson says.—*New York Herald Tribune*, October 19

BY THE CLOCK?

Doctor: "How often does the pain come?"

Patient: "Every four or five minutes."

Doctor: "And lasts?"

Patient: "Well, a quarter of an hour, at least."

FAMILY AFFAIR

Doctor: "Only relatives are allowed to see him. Are you a member of his family?"

Girl: "Oh, I'm his sister."

Doctor: "Oh, really? I'm so glad to meet you. . . I'm his father."

STUDIES IN THROMBO-EMBOLIZATION

II:* Observations on the Use of Dicumarol† (3,3' Methylenebis (4-Hydroxycoumarin)) in Embolization. Report of Five Cases

SHEPARD SHAPIRO, M.D., and BENJAMIN SHERWIN, M.D., New York City

THE recent series of publications by Link and his associates^{1,2,3,4,5} of the Wisconsin Experiment Station reveal an outstanding work in which they isolated, identified, and synthesized the causative agent of the hemorrhagic sweet clover disease of cattle.^{6,7,8,9,10} They showed that when the substance 3,3' methylenebis (4-hydroxycoumarin), which they isolated from spoiled sweet clover hay,¹ is introduced into the body, it produces the following effects:

1. It decreases the prothrombin level (or activity).
2. It prolongs the whole blood coagulation time.
3. When given to healthy experimental animals (in therapeutic doses, intermittently), it apparently does not give rise to permanent injury.
4. When given continuously (in adequate doses), it induces the hemorrhagic phenomena characteristic of the sweet clover disease.

By virtue of the above characteristics 1, 2, and 3, this compound promises to be of value in the control and treatment of thrombotic and thrombo-embolic processes.

Preliminary reports of experimental and clinical trials with this *in vivo* anticoagulant have recently appeared.^{11,12} In this communication are recorded observations in which it was used in pulmonary thrombo-embolization and to prevent the development of emboli.

In July, 1940, shortly after the synthesis of the substance was realized, one of us (S. S.) had the opportunity to discuss the possible therapeutic use of this compound with Professor Link and his associates. After its activity was demonstrated,^{11,12} through the kindness of Professor Link we obtained a supply of the 3,3' methylenebis (4-hydroxycoumarin).

The prothrombin time of the blood plasma was estimated by the technic described by Shapiro, Sherwin, Redish, and Campbell,¹³

which is an extension of the method described by the Wisconsin group.² It takes into consideration the prothrombin time of (a) whole plasma, (b) diluted plasma, and (c) the difference between these two. By this procedure it has been possible to determine an optimum point for therapeutic effect free of the danger of bleeding.

Briefly stated this is the procedure (see Table 1):

(A) Using thromboplastin-calcium chloride mixture:² 4.5 ml. fresh blood obtained by venipuncture are added to 0.5 ml. M/10 sodium oxalate. Clear plasma is obtained by centrifuging. 0.1 ml. whole plasma kept at 37 C. is quickly added to 0.2 ml. thromboplastin-calcium chloride mixture (also at 37 C.) and the time which elapses before the fibrin clot forms is noted with a stop watch. The identical procedure is then repeated, using 0.1 ml. of 12.5 per cent plasma in place of whole plasma.

(B) Using snake venom:¹⁴ 0.1 ml. whole plasma is added to 0.1 ml. venom and placed in the constant temperature bath at 37 C. for five to ten minutes. To this is quickly added 0.1 ml. M/40 calcium chloride which has been kept at the same temperature, and the time elapsing before the fibrin clot formation is noted with a stop watch. The same procedure is repeated with 0.1 ml. of 25 per cent plasma in place of whole plasma.

Estimates are done in duplicate.

It has been found by this method that a safe and effective dosage level is that at which the diluted plasma prothrombin time is markedly prolonged (two to three times normal), while that of the whole plasma is only moderately extended (not to exceed double the normal value). It has been found that as the concentration (or activity) of prothrombin decreases, the difference between the whole and diluted plasma prothrombin time increases. It has also been found that increase in the plasma prothrombin level (or activity) is a factor which causes a reduction in the extent of the difference between the prothrombin time of whole and that of diluted plasma.

Serial estimations of prothrombin after surgery have revealed the following facts: Com-

From the Department of Surgery, Lincoln Hospital, Kirby Dwight, M.D., Director.

* Paper I of this series was published in the *Annals of Surgery* 116: 175 (August) 1942.

mencing about the fifth or sixth day after operation and occurring as late as the twelfth or fourteenth postoperative day, there is a more or less sudden shortening of the difference between the prothrombin time of whole and diluted plasma, due chiefly to a reduction of the prothrombin time of the diluted plasma. Statistics have shown that this is the interval when postoperative thrombo-embolization most commonly occurs. It was found further that in those instances in which pulmonary infarction had developed the difference in prothrombin time between that of whole and diluted plasma had become reduced to a point below that of normals.¹⁴

The reports of Jorpes and of Murray have shown that anticoagulant therapy may be effective in both the prevention and treatment of thrombotic processes.¹⁵ They used heparin, a substance which must be given by continuous intravenous administration, which

in certain individuals causes adverse reactions, and which is costly in price. Dicumarol, which was used in the present series, is given by mouth, causes no ill effects (as far as is known) in proper dosage, and is low in cost. The procedure for prothrombin estimation herein described is well suited for following the dosage levels of Dicumarol.

In this report are presented 5 cases of embolization treated with Dicumarol. The purpose of this treatment was primarily to prevent further embolization.

Case 1.—H. F., a 32-year-old white woman, was subjected to a pelvic repair and dilatation and curettage on December 1, 1941. Two days later a fever arose, varying between 99 and 100.5 F. On the third day tenderness over the right saphenous vein was observed. The temperature increased to 101.5 F. On the sixth postoperative day the patient was suddenly seized with a sharp pain in the left axilla. She became

CHART 1. (Case 1) Represents temperature curve and differences (seconds) in prothrombin time between whole and diluted (25 per cent) plasma. Snake venom was used. Normal mean difference = 10.5 seconds. Note shortened difference at time of pulmonary infarction. S = Sulfathiazole. 200 and 100 mg. dosages = Dicumarol.

CHART 2. (Case 2) Temperature curve and simultaneous differences in prothrombin time between whole and diluted (25 per cent) plasma. Snake venom was used. Note progressive shortening of prothrombin time differences preceding and at time of pulmonary infarction. S = Sulfathiazole. 400 and 300 mg. dosages = Dicumarol.

pale and developed shallow, rapid respirations of about 40 per minute and thready pulse of about 170 per minute. There was heard a pleuritic rub and many moist rales over this area. Pulmonary infarction was believed to have occurred, involving the left lower lobe. Sulfathiazole was administered by mouth. The temperature receded, becoming normal within about two days. On December 10 (eighth postoperative day) there was a sudden recurrence of the pain in the left chest, followed by the appearance of dullness, distant breath sounds, and pleuro-pericardial friction rub. The temperature was 103.8 F. An electrocardiogram did not reveal a pattern indicative of coronary artery occlusion. The diagnosis of pulmonary infarction (second episode) was made, and the sulfathiazole (which had not been withdrawn) was continued. The fever acquired an intermittent character, rising to 102.4 F. each day. On December 15, the following findings were noted: The patient appeared toxic. Both right and left saphenous veins were palpably thickened and tender, with the overlying skin red and edematous. The lower abdomen bilaterally was considerably tender. The temperature was 102.6 F. The heart rate 130 per minute, and of regular rhythm. No murmurs were heard. Over the base of the left lung there was noted dullness, diminished breath and voice sounds, and limited descent of the diaphragm. A few fine and large moist rales were audible over this area. The blood pressure was 120/80. No abnormal constituents were found in the urine. The difference in prothrombin time between that of whole and

diluted (25 per cent) plasma¹⁴ was 2.5 seconds (normal 10.5 seconds). The platelet count was 350,000.

The diagnosis was bilateral saphenous vein thrombophlebitis and thrombo-embolization of the lower lobe of the left lung with resulting infarction.

Dicumarol was given orally for eight consecutive days. The dosages and prothrombin differences and restoration are depicted in Chart 1. Sulfathiazole was continued during the entire period.

The first change observed was an alteration in character of the temperature curve, which began to flatten simultaneously with the initial prolongation of prothrombin time. Within about one week the physical signs in the left lung cleared, and the temperature became normal and remained at this level. No evidences of additional emboli appeared. Six months later the patient reported that she was well and had been asymptomatic in the interval.

Case 2.—S. G., a white man 29 years of age, was operated upon December 8, 1941, for an umbilical hernia. A moderate febrile temperature occurred following operation and receded after the discharge of serum from the wound when the sutures were removed on the sixth day. On the tenth postoperative day the patient was suddenly seized with severe cutting pain in the left lower axilla. Accompanying this was rapid, shallow breathing and expectoration of a slight amount of blood-tinged sputum. There were diminished breath and voice sounds, and a few moist rales were noted over the base of the left

CHART 3. (Case 3) Temperature curve and differences (seconds) in prothrombin time between whole and 12.5 per cent plasma. Thromboplastin-calcium chloride mixture used. Normal mean difference = 18.5 seconds. 300, 200, and 100 mg. dosages = Dicumarol.

lung posteriorly. Pulmonary infarction was believed to have occurred and sulfathiazole was administered by mouth. Within one week the temperature became normal and the physical signs in the chest cleared almost entirely. No evidences of thrombophlebitis were detected.

On December 23 prothrombin estimations¹³ were made. These were repeated on succeeding days, as noted in Chart 2. The difference between the prothrombin time of whole and diluted plasma (25 per cent) diminished from 8 seconds on December 25 to 2 seconds on the following day. On December 27, there was sudden recurrence of the sharp pleuritic pain, tachycardia, rapid, shallow breathing, and temperature of 101.8 F. Numerous moist rales, impaired resonance, and distant broncho-vesicular breath sounds were heard over the left lung posteriorly, extending from the angle of the scapula to the base of the lung. It was believed that a second episode of pulmonary infarction had taken place. This was confirmed by a roentgenogram of the chest. Sulfathiazole therapy was continued, and on December 28 oral administration of Dicumarol was started. An irregular pyrexia persisted until December 31, after which it began to recede, reaching normal on January 3 and remaining at this level. Within one week all abnormal physical signs in the left lung cleared. The effect upon prothrombin time by Dicumarol as indicated by the extent of the difference between whole and diluted (25 per cent) plasma is shown in Chart 2.

The urine was consistently free of abnormal constituents. On December 22, hemoglobin was 14 Gm.; red blood cells 4,992,000; white blood cells 22,600; segmented neutrophils 80 per cent; nonsegmented 7 per cent; lymphocytes 10 per cent; eosinophils 3 per cent. On December 26 the white blood cell count was 15,500; segmented neutrophils 65 per cent; nonsegmented 1 per cent; eosinophils 4 per cent; lymphocytes 29 per cent; basophils 1 per cent. No additional emboli were detected after the Dicumarol effect became discernible in the prothrombin estimations. The patient was seen four months later. He was symptom-free and reported that he had been well during the intervening period.

Case 3.—J. K., a 58-year-old white woman, developed a dull ache in the left thigh on February 26, 1942. The pain grew worse and the thigh became red and swollen on its inner surface. On March 3 a diagnosis of saphenous vein phlebitis was made. The patient was put to bed and continuous wet dressings were applied to the area.

The past history was irrelevant, except that the patient had had varicose veins for several years and about eighteen months previously had been confined to bed for five weeks owing to "inflammation of the left lower leg."

The patient was obese, the lungs were clear and resonant throughout, the heart was regular and presented a systolic murmur at the base. The blood pressure was 150/90.

Over the left thigh there was redness and

CHART 4. (Case 4) Differences in prothrombin time between whole and diluted plasma. Dosages indicated are of Dicumarol.

edema and tenderness along the course of the saphenous vein.

On March 7 there occurred suddenly a sharp pain over the right chest, tachypnea, expectoration of blood-tinged sputum, and a rise in temperature to 101 F. There were heard diminished breath sounds in the right paravertebral region of the right base. A diagnosis of pulmonary embolus and infarction was made. X-ray examination supported this opinion. On March 10 there was broncho-vesicular breathing and dullness over the midportion of the right chest posteriorly. The left saphenous vein showed redness, tenderness, and swelling over its course. Dicumarol was administered orally, beginning March 10. On March 14, the plebitis of the left saphenous vein was less pronounced; the redness and swelling were especially diminished. Over the right lower chest were heard impaired resonance and numerous moist rales.

On March 21, there was still blood-streaked sputum, and a few moist rales were heard over the right base, although the x-ray film of the chest revealed almost complete clearing of the previously noted shadow (infarct).

The temperature curve, shown in Chart 3, reached the height of 102.8 F. on March 9 and gradually fell to normal by March 12, at which level it remained, with the exception of an unexplained rise to 102.8 F. for several hours on March 16.

On March 25, the evidence of pulmonary pathology had completely cleared, the temperature continued to be normal, the expectoration of blood-stained sputum had ceased, and the left saphenous vein was palpably thickened but free of evidences of acute inflammation.

The urine on several occasions showed rare granular casts and a few red and white blood cells. The specific gravity varied between 1.002 and 1.008 during the entire period of observation.

The blood count on March 9 was 78 per cent hemoglobin; red blood cells 4,030,000; and white blood cells 12,000; segmented neutrophils, 74 per cent; nonsegmented 1 per cent;

lymphocytes 17 per cent; monocytes 7 per cent; eosinophils 2 per cent. Platelets numbered 400,000. On March 31, the platelets were 250,000. The blood chemistry (serum proteins, cholesterol, nonprotein nitrogen, and sugar) were all normal. Chart 3 shows the difference between the prothrombin times of whole and 12.5 per cent plasma during the period of Dicumarol feedings.

No additional emboli were observed after the Dicumarol was administered.

Case 4.—A. L. was a 45-year-old white man who had been under treatment since August, 1941, for subacute bacterial endocarditis (*streptococcus viridans* bacteremia) which had become engrafted upon a rheumatic valvulitis. Sulphanyl compounds were well tolerated; hence the patient received these almost continuously from the time of onset in August.

The findings on December 31, 1941, were as follows: A chronically ill, pale man showing numerous petechiae distributed throughout the skin, especially that of the fingers, and in the conjunctivae. The spleen was enlarged and extremely tender (recent embolization); the liver was palpable three fingerbreadths below the free margin of the ribs. The heart was enlarged, accelerated, and of regular rhythm. Aortic diastolic and mitral systolic and presystolic murmurs were present. A few basal moist rales were heard over both lungs. An electrocardiogram showed regular sinus rhythm, left axis deviation, and prolongation of the P-R interval. The hemoglobin was 72 per cent; red blood cells 3,450,000. Because the patient was showing evidences of frequent embolization (almost daily) it was decided to administer the *in vivo* anticoagulant in an effort to lessen this.

Dicumarol feedings were instituted on December 31, 1941. The patient received a total of 4 Gm. in three months, until March 30, 1942, when he died of heart failure. He lived out of the city and consequently it was possible to obtain plasma for prothrombin estimations only at intervals of several days. These estimations were made by the method above described. The

CHART 5. (Case 5) Platelet and prothrombin time of whole and 12.5 per cent plasma. (Thromboplastin-calcium chloride used.) The first 100 mg. intravenously was given on the same day as the 400 mg. by mouth. Note almost identical responses to 600-mg. dosages and greater response to initial 700-mg. dosages.

estimations on December 31, 1941, showed a difference between the time of whole and diluted (25 per cent) plasma of 3 seconds (normal 10.5 seconds). This difference was maintained at a level of between 20 to 33 seconds during the period of treatment (see Chart 4). No bleeding phenomena arose at any time. The cessation of emboli within one week after the anticoagulant therapy was started was striking. Evidences of heart failure became increasingly prominent and the patient died as a result of this and not of embolization. No necropsy was done. In the three months' interval of Dicumarol treatment there was discerned only one embolus (splenic infarct), whereas the organisms were present almost daily before the therapy was initiated.

The fever was not altered; therefore it was felt that the anticoagulant did not influence the sepsis, although the frequency of embolization became markedly reduced after the Dicumarol feedings.

On February 16 the total serum protein was 6.26 Gm. per 100 ml. The albumin was 3.68 Gm.; the globulin 1.35 Gm.; and fibrinogen 0.51 Gm. per cent. The A/G ratio was 2.7 to 1 and the total cholesterol 207 Gm. per 100 ml.

Case 5.—C. B., a 41-year-old white woman,

was delivered of a full-term normal baby on March 1, 1942. The pregnancy and delivery were not unusual. On the sixth postpartum day the temperature rose to 102.5 F. and remained irregularly elevated, reaching 103 F. and 104 F. on the eleventh and twelfth days after delivery, respectively, and at which time the right saphenous vein appeared to be acutely inflamed. Sulfathiazole therapy was then started. On the sixteenth postpartum day the temperature was still elevated and evidences of saphenous thrombophlebitis were still prominent. A prothrombin estimation by the above method¹³ was done and found to be normal. On the eighteenth day this was repeated and the difference between the prothrombin time of whole and diluted (12.5 per cent) plasma was reduced to 7 seconds. During the same day the patient was suddenly seized with severe sharp pain in the right axilla. Her respirations became shallow and very rapid and she coughed up bright red blood. Dullness, diminished breath and voice sounds over the right base, and limited descent of the right diaphragm were noted, and consequently it was believed that the patient had suffered an infarction of the lower lobe of the right lung. The roentgenogram supported this diagnosis. Dicumarol

was administered as follows: 400 mg. intravenously on each of the next two days (see Chart 5). A transfusion of 300 ml. fresh blood was given also. Sulfathiazole was continued. The temperature fluctuated irregularly between 100.5 F. and 102 F. until the ninth day after the transfusion, when it rose to 104 F. At the same time there appeared an erythematous and urticarial eruption and swelling and redness of several joints, especially both wrists. It was believed that these symptoms were indicative of serum (transfusion) reaction. Two daily doses of 300 mg. each of Dicumarol were given by mouth at this time. The fever subsided within three days to normal, and the skin eruptions and joint effusions also disappeared. The sulfathiazole was withdrawn. During this period there was little change in the physical signs in the right chest. On the seventeenth day after the infarction the temperature again gradually rose despite sulfathiazole administration. The fever continued, varying irregularly between 99 F. and 101 F. The prothrombin estimations were normal and two additional doses of 300 mg. of Dicumarol each were given (see Chart 5). The irregular fever did not recede; physical signs in the right chest suggested a fluid accumulation and on the twenty-sixth day after the infarction about 50 ml. of slightly cloudy amber fluid were removed. This was sterile on culture. A leukocyte count at the time was 4,000 per cmm., and the sulfathiazole was therefore discontinued. The temperature then gradually fell to normal for three days, after which it assumed a low-grade febrile curve varying between 99.8 F. and 101 F. Evidences of an interlobar effusion were detected.

The right saphenous thrombophlebitis had been marked, extending throughout the entire course. Following the first Dicumarol effect upon the blood there occurred a striking recession of this inflammatory reaction, and gradually all evidences of it completely disappeared, without residual interference with the return flow of blood in the limb.

It is apparent that the course of the infarction was unaltered by the anticoagulant therapy. However, emphasis is placed upon the fact that no further embolization was detected after Dicumarol was administered.

There was noted a depression of the serum proteins during the febrile period. In an effort to counteract this protein, hydrolysate (aminoids)¹³ were given perorally. Restoration of the total proteins to a normal level was observed within two weeks despite the continued fever. This has been our experience in other toxemias and is the subject of another study. The protein hydrolysate did not influence the anticoagulant effect.

The urine remained free of abnormal constituents during the entire period of observation.

Discussion

Whatever the causes initiating thromboses

may be, one thing is clear; namely, that if the blood is prevented from clotting, the thromboses cannot occur. The coagulation of blood is a continuous process made up of several consecutive reactions, each dependent upon the commencement of its predecessor for its own initiation. Consequently, by blocking any stage the culmination of all of these phenomena—that is, the formation of the clot—can be prevented. Hence, by its effect upon prothrombin, Dicumarol inhibits blood coagulation. In proper dosage it may be applied therapeutically. Its virtues are its ease in administration, its low price, the fact that it can be given over a long period of time *intermittently* without apparent ill effect, and that its effective dosage level can be reliably estimated and the hazard of bleeding avoided. This substance becomes measurably active only after a latent period of from twelve to twenty-four hours.

In 5 cases herein reported emphasis is placed upon the immediate cessation of embolization following adequate Dicumarol effect upon the prothrombin level (or activity). There is, of course, the possibility that this occurred independently of the therapy; however, the demonstration was so striking that it appears that the anticoagulant was responsible for the prevention of further embolization.

The prompt disappearance of the inflammatory reactions about the veins in Cases 1, 3, and 5 after the use of Dicumarol demonstrates that this therapy may also be of value in the treatment of acute thrombophlebitis.

The serial prothrombin estimations in Cases 2 and 5 revealed the reaction previously observed;^{13,14} namely, that about one or two days preceding the appearance of signs of pulmonary infarction the difference in prothrombin time between that of whole and diluted plasma becomes reduced to a point below that seen in normal persons.

It appears that Dicumarol acts on the prothrombin elaborating mechanism (liver?). It is therefore especially important that the serum proteins be maintained at a normal level. Consequently, it seems advisable to give a high protein diet during the period of toxemia while Dicumarol is being administered. Based upon the work of Beling and Lee¹⁵ we have been feeding protein hydrolysate in these cases.

Summary and Conclusions

The *in vivo* anticoagulant 3,3' methylenebis (4-hydroxycoumarin), commonly designated

as Dicumarol, may be safely administered to man.

A safe and therapeutically active dosage level is described by its respective effects upon whole and diluted plasma prothrombin time.

Five cases of embolization are reported. In 4, emboli ceased entirely, and in one they were strikingly diminished after Dicumarol therapy. In three instances in which acute thrombophlebitis was also present, it was observed that the signs of this inflammation subsided promptly after the anticoagulant effects became established.

No early or late toxic manifestations were observed.*

The oral Dicumarol was supplied by Dr. K. K. Chen of Eli Lilly & Co., Indianapolis, Indiana, and the intravenous preparation by the Abbott Laboratories, North Chicago, Illinois. Dr. Samuel Gordon (now a Major in the U.S. Army), of Endo Co., Richmond Hill, New York, supplied reagents used in the procedures. The protein hydrolysate (aminoids) was supplied by Arlington Chemical Co., Yonkers, New York.

Miss Frances Kaufman gave technical assistance.

WORSE FOE TO JAPS

Members of the WFA attending their first national officers training school got a lesson on how to fight stomach cancer and learned that this highly fatal disease attacks Japs two or three times as often as it does members of the white races.

Teacher of this class for officers of the Women's Field Army of the American Society for the Control of Cancer was Dr. George T. Pack, attending surgeon, Memorial Hospital, New York.

"Cancer of the stomach occurs two or three times as frequently in the Japanese as it does in the white races, a phenomenon not entirely understood, but highly approved of, at this time," he stated.

The stomach is the most common region of the body for fatal cancer to be located, he said.

The "flagrancy of high pressure salesmanship through the radio and the press by manufacturers of proprietary drugs in order to induce the public to treat its own indigestion" is one of four causes for the high mortality from stomach cancer listed by Dr. Pack.

The other three are the naturally high and increasing incidence of this disease; the progress of these cancers to the stage of inoperability before the majority of them are correctly diagnosed; and the difficulties attending surgical removal of cancer in this organ.

In two-thirds of the cases the patients are to blame for "immoderate and fatal delay" in getting a correct diagnosis and early, appropriate treatment. In the other third, Dr. Pack said, it is the fault of the physician first consulted.

On the encouraging side, Dr. Pack pointed out that many cancers of the stomach, formerly considered inoperable and hopeless, are now successfully removed. He reported that in the last two years 16 patients at Memorial Hospital have had the entire stomach removed because of cancer.

In this operation, the small intestine is stitched to the esophagus or gullet, and serves as a substitute stomach, enabling the patient to eat normal meals. In most patients, removal of part of the stomach is all that is necessary.—*Science News Letter*, October 3, 1942

Hush, little doctor, don't you cry,
You'll be a soldier by and by.—*Selected*

A bachelor is a man who has no children—to speak of.

THE ROLE OF THE LIVER IN SURGERY

ALLEN O. WHIPPLE, M.D., New York City

THE liver is the largest and most complex organ in the body, performing a larger number and a wider variety of functions than any other, and in many of these functions having an amazing margin of safety. Because of these many functions and the variable safety factor, there is no one test for liver function as a whole. Moreover, considerable uncertainty and lack of agreement prevails, not only among the clinicians but among the physiologists, as to the value of the tests that are commonly employed for the several known functions of this great organ.

In order to simplify the discussion of the relation of surgical procedures to liver physiology and liver pathology, let us consider the liver lobule, which is the lowest functional common denominator.

A branch of the hepatic artery delivers arterial blood to the tubes of liver cells in the lobule. The portal vein ends in capillary branches which pass between the columns of liver cells to converge in the central hepatic vein in the center of the lobule. The columns of liver cells separate the portal capillaries from the primary bile ducts or bile capillaries. Between these blood and bile capillaries the liver cells perform their various functions. Some of the products of these functions pass into the bile capillaries; others pass into the vascular channels, to be carried to the hepatic veins and into the cava. Disturbances in liver function may arise in the blood supply from the hepatic artery or from the portal vein, or from infection or obstruction in the bile ducts and, most important, in the liver cells that have so many functions. These liver cells may be involved in acute inflammatory and degenerative processes with acute and overwhelming symptoms, or they may be the site of chronic inflammatory and degenerative changes that result in slow connective tissue replacement and slow progressive or stationary symptoms, depending upon the remarkable powers of the liver cells to regenerate.

The functions of the liver that, when disturbed, may require surgery or that may become disturbed as a result of, or in the course

of, surgical therapy are: (1) bile formation, (2) formation of organic substances involved in blood coagulation, and (3) metabolism and storage of carbohydrates, proteins, and fats, and the production of antitoxic and protective substances.

1. Bile Formation

Bile is an alkaline fluid containing as its most important components bile pigments, bile salts, and cholesterol. The bile pigments are bilirubin and its oxidized product, biliverdin. Bilirubin is made not by the liver cells but in the circulating blood by the reticulo-endothelial system, including that in the liver, from the hemoglobin of broken-down red cells. This bilirubin is normally removed from the circulating blood plasma by the liver cells and passes into the bile capillaries with the bile. That is, bilirubin is excreted in the bile unless it is brought to the liver in excessive amounts, as in hemolytic jaundice, or unless the liver cells are so damaged as not to be able to pass it on into the bile capillaries. Before it passes through the liver cells the bilirubin is spoken of as "prehepatic" or R-E bilirubin.

In passing through the liver cells, bilirubin is changed from a colloid to a crystalloid by the removal of a protein molecule. In this form, which is known as posthepatic bilirubin, it is excreted by the kidney. In jaundice with posthepatic bilirubin in the urine the serum van den Bergh test is direct, whereas in acholuric jaundice with prehepatic bilirubin in the blood the van den Bergh reaction is indirect. Therefore, the urine examination for bilirubin yields the same information as the van den Bergh test, and because it is a much simpler test for differentiating between pre- and posthepatic bilirubin, it has displaced the van den Bergh test in many clinics as a means of differentiating between obstructive and non-obstructive or hepatogenous jaundice.

Phosphatase as an enzyme is produced in bone, carried into the blood, and excreted by the liver in the bile. Therefore it is so markedly increased in obstructive jaundice that it tends to run parallel with the rise in serum bilirubin and may reach the level of 30 Bodansky units. In nonobstructive jaundice, however, in spite of the rise in serum bilirubin the alkaline serum phosphatase does not increase

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1942.

From the Department of Surgery, College of Physicians and Surgeons, Columbia University, and the Surgical Service, Presbyterian Hospital, New York City.

FIG. 1.

above the level of 10 Bodansky units. Other conditions in which high serum phosphatase readings are found, such as hyperparathyroidism, bone tumors, and carcinoma of the prostate, have to be ruled out in this test, but in such conditions jaundice is seldom present.

Bile Salts.—Taurocholic and glycocholic acids, and their sodium and potassium salts, are made in the liver, pass out with the bile, but are reabsorbed through the intestine and returned to the liver. The bile salts have important functions. They assist in the absorption of the products of fat cleavage, assist the digestive action of the pancreatic enzymes in the intestine, keep the cholesterol in the bile in solution, stimulate the liver to produce bile, and finally are essential for the absorption of vitamins D and K. It is evident, then, that a continuous flow of bile is essential and that failure of bile salt production in the liver or failure of bile salts in the bile to enter the intestinal tract gives rise to serious consequences.

In a liver that has been damaged by infection, cellular degeneration, or biliary obstruction, the bile acid content is decreased and the chloride content is increased. Therefore the study of bile from a common duct drain for the relief of common duct obstruction for its bile salts and chloride content is of value in determining liver damage or the return of normal liver function in bile production.

The importance of restoring the flow of

bile into the intestinal tract is evident because of the role of bile salts in fat digestion and vitamin D and K absorption. For this reason a permanent biliary fistula must by all means be avoided.

A most important but simple method for estimating the progress and determining the prognosis in a patient who has been operated upon for common duct obstruction with common duct drainage is the daily recording of the triad of (1) the degree of jaundice, as determined by vision, or, more accurately, by serum bilirubin determinations, (2) the color of the stools, and (3) the amount of bile drainage. It is obvious that with the decrease of jaundice, the resumption of brown color in the stools, and a steady decrease or cessation of bile drainage the patient is making a satisfactory recovery. On the other hand, decreasing jaundice, clay-colored stools, and a continued flow of 700 to 1,000 cc. of bile from the common duct drain mean only one condition—a common duct obstruction below the site of the drain. For accurate determination of the degree of jaundice and the increase or decrease of jaundice from day to day, the serum bilirubin determination is the most reliable test.

For the diagnosis of gallbladder disease and gallstones, an accurate history and careful physical examination are still the reliable methods they have always been. In doubtful cases we have found that the study of duodenal bile obtained by intubation gives as accurate data as cholecystography in the diagnosis of gallstones. The presence of cholesterol crystals and calcium bilirubinate particles in the centrifuged bile is positive evidence of gallstones. Failure of the dye to concentrate in the gallbladder in the cholecystogram may mean disturbed physiology, but it does not necessarily indicate a diseased gallbladder or adequate reason for a cholecystectomy.

2. Formation of the Organic Substances Involved in Blood Coagulation

It is now generally agreed that four substances are required for the clotting of blood: (1) prothrombin, (2) thromboplastin, (3) fibrinogen, and (4) calcium. The first three of these, organic in nature, are made in the liver. Calcium and fibrinogen are not materially altered in the bleeding tendency associated with jaundice or cholemia. Prothrombin is the substance that, when deficient, causes bleeding. Its formation in the liver is closely related to vitamin K. Depletion of

prothrombin is the result of lack of the fat-soluble vitamin K or is due to the failure of the vitamin to be carried across the intestinal mucosa owing to the absence of bile acids in the intestine. Thus there may be a prothrombin deficiency either as a result of severely damaged liver cells or of the failure of vitamin K to reach the liver because of lack of bile salts in the intestinal tract. Jaundice, as such, is not the cause of deficient prothrombin, for a patient who has a complete, permanent external biliary fistula and who is jaundice-free will show a marked hypoprothrombinemia and severe bleeding tendency.

The Quick test for the blood prothrombin level is a most important determination in every case of jaundice or suspected liver deficiency. Prothrombin cannot be stored in the liver but can be rapidly depleted, especially if vitamin K fails to reach the liver. Prothrombin deficiency should be treated by the administration of vitamin K and of bile salts for several days before operation and several days after operation until normal bile flow is established in the intestine. If the prothrombin level in the blood is below 15 per cent, an immediate transfusion of fresh whole blood is indicated. The more recent use of the synthetic naphthoquinones, with properties similar to vitamin K, given by vein or intramuscularly, effects equally good and more immediate elevation of prothrombin levels. Dr. Andrus and Dr. Lord of the New York Hospital have used 2-methyl-1,4-naphthoquinone intramuscularly as an effective means of raising the prothrombin level when oral administration of vitamin K and bile salts was difficult.

3. Metabolism and Storage of Carbohydrates, Proteins, and Fats; Production of Antitoxic and Protective Substances

The liver cells have a major function in the metabolism and storage of carbohydrates, proteins, and fats, and in the production of antitoxic and protective substances against kidney and central nervous system damage. Adequate protein and carbohydrate (glycogen) storage is essential in the prevention of liver cell damage, whereas an excess of lipid content in the cells favors liver damage. For these reasons it is essential, as Ravdin and his associates have so ably demonstrated, that patients facing major surgical procedures, especially those involving the biliary system and the gastrointestinal tract, be given a high protein, high carbohydrate diet before and after operation—namely, a diet composed of

approximately 70 per cent carbohydrate, 25 per cent protein, and not more than 5 per cent fat, and containing from 3,000 to 3,500 calories. Such a diet may require both the oral and intravenous routes, and, in some cases, feeding by the intestinal tube. Such a diet will prevent liver damage by protein loss and will prevent general body weight loss.

Certain tests are now fairly well demonstrated as having a bearing upon the healthy state or the damaged condition of the liver cells. The sugar (galactose) tolerance tests determine the ability of the liver to metabolize carbohydrates. The dye excretion tests—bromosulfalein and rose benzol—are an indication of the ability of the liver cells to excrete foreign dye substances through the bile, and, in the absence of jaundice, are practical tests for liver cell damage. The determination of the bile salt and sodium chloride content of the bile, as obtained by duodenal tube or from a common duct drain, is a valuable and accurate measure of liver cell bile production and in determining the progress of a postoperative biliary case.

The Quick hippuric acid test of liver function is based upon the conjugation of glycine and benzoic acid, in which process the latter is detoxified. This conjugation results in the formation of hippuric acid by the kidney, but the required glycine is formed only in the liver. Liver damage impairs glycine synthesis with benzoic acid and reduces the output of hippuric acid. This hippuric acid test is considered by many to be the most valuable for determining liver cell damage and for estimating surgical risk and determining prognosis. Impaired kidney function compromises the usefulness of the test.

The Hanger cephalin flocculation test,¹ which has recently attracted wide attention, is, in our experience, one of the most useful tests for determining acute liver damage such as is seen in acute hepatitis and acute and sub-acute yellow atrophy, and in differentiating the hepatogenous jaundice seen in acute hepatitis from obstructive jaundice. This test indicates irritation of the cells of the liver by disease, and is not necessarily dependent upon impairment of any one liver function. Positive reactions are due to some subtle changes in the globulin fraction of the serum that is present in many types of inflammation and acute degeneration in the liver cells. The test consists of adding a colloidal suspension of cephalin and cholesterol to the patient's serum which has been diluted 1 to 21 with normal salt solution. After twenty-four to

forty-eight hours the degree of flocculation and precipitation of the lipids is noted in the test tube. The serums of normal individuals or of patients with diseases not accompanied by active inflammation or degeneration cause no flocculation. Cases of acute hepatitis or of active cirrhosis usually give a strong (4 plus or 3 plus) reaction, which becomes negative as the hepatic disorder subsides. For this reason this test is a valuable aid in determining the course and the prognosis in the disease.

In the medical and surgical clinics of the Presbyterian Hospital this test, in combination with the alkaline serum phosphatase test, has proved of great value in differentiating hepatogenous from obstructive jaundice. I quote from Dr. Gutman's and Dr. Hanger's recent article in the *Medical Clinics of North America*:

"Thus far, both tests have not been found to be in error in any one case either of 'catarrhal' jaundice or of jaundice due to demonstrated common duct obstruction. Our experience indicates that, in general, (1) the diagnosis of common duct obstruction is highly improbable if the alkaline serum phosphatase level is *below* 10 Bodansky units and the cephalin flocculation test is strongly *positive*; (2) the decision to explore icteric patients, based on clinical grounds, is supported by finding a serum phosphatase level *over* 10 Bodansky units associated with a *negative* cephalin flocculation reaction."²

For further discussion of these tests, those interested are referred to this recent paper.

Rosenberg and Soskin³ have more recently reported their results in using the cephalin flocculation test. In this work 100 patients with unequivocal clinical evidence of mild or moderate degrees of liver damage were studied. In these patients the results with this test were compared with various commonly employed criteria of liver function, including determinations of icterus index, bromosulfalein retention, hippuric acid excretion, serum cholesterol partition, serum albumin and serum globulin fractions, and prothrombin time. It was found that the cephalin flocculation test gave by far the best correlation with clinical observations of any of the tests or criteria of liver function and was positive in 98 per cent of the 100 cases. In 10 patients tests were positive when all other tests and combination of tests were negative.

This combination, therefore, of the cephalin flocculation test with the serum phosphatase test for differentiating hepatogenous from obstructive jaundice is certainly the most valuable for the surgeon in determining which jaundiced cases should be operated upon. For in many cases this decision is not easy to make or cannot be made definitely without such laboratory confirmation.

MARY PUTNAM JACOBI FELLOWSHIP

The Women's Medical Association of New York offers a Mary Putnam Jacobi Fellowship for medical research, of one thousand dollars (\$1,000), available October 1, 1943. It is open to any woman doctor, either American or foreign, who is a graduate of a reputable medical school.

Applications for this fellowship must be filed with the secretary of the committee by March 1, 1943, and must be accompanied by statements by persons other than the candidate as to (1) health, (2) educational qualifications, and (3) previous work. The applicant herself should state the problem she proposes to investigate and send her photograph. As it is not practicable for the secretary to write for letters about candidates, applicants should send with their applications sufficient data to enable the committee to judge of their respective merits.

The recipient of the fellowship will be expected

to give full time to the study of her problem and to make a report for publication at the completion of her research.

Application blanks may be obtained from the secretary of the committee.

ANNIE S. DANIEL, M.D.

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the February 1 issue and will concern "Management of Peptic Ulcer: II. Surgical Aspects."

The Management of Peptic Ulcer: I. Medical Aspects

DR. McKEEN CATTELL: This is the first of two conferences on the subject of the management of peptic ulcer. Today we will consider the medical aspects of treatment.

Dr. Summerson will begin with a discussion of the properties of the antacids.

DR. WILLIAM H. SUMMERSON: When the biochemist considers the various antacids which clinicians have been using for the relief of gastric hyperacidity, he finds that they are of two general types.

One type, which we may call the *nonbuffer antacids*, is represented by such substances as the carbonates, oxides, and hydroxides. These compounds react with equivalent amounts of acid to form an essentially neutral solution, the reaction involving the formation of neutral salts and either water or readily volatile carbon dioxide. The other type, the *buffer antacids*, does not produce a neutral solution but lowers gastric acidity by replacing the relatively strong hydrochloric acid of the gastric juice with much weaker acids. The buffer antacids include such substances as the citrates, acetates, phosphates, and silicates. These compounds differ decidedly from the nonbuffer antacids in the manner in which they combat gastric acidity.

This difference between the buffer and nonbuffer antacids is illustrated by a comparison of the neutralizing value of the various antacids. The neutralizing value is defined as the dose of the substance, in grams, that corresponds to effective neutralization of one liter of tenth-normal hydrochloric acid. This amount of acid was selected because under these conditions the neutralizing value of the antacid approximates the usual therapeutic dose. The neutralizing values for some of the more commonly used nonbuffer antacids are given in Table 1.

The compounds listed in Table 1 all produce

TABLE 1.—NEUTRALIZING VALUE OF CERTAIN NON-BUFFER ANTACIDS

Compound	Grams Needed to Neutralize 1 Liter of N/10 HCl
Magnesium oxide U.S.P.	2.0
Magnesium carbonate U.S.P.	4.9
Calcium carbonate U.S.P.	5.0
Sodium carbonate anhydrous	5.3
Sodium bicarbonate U.S.P.	8.4
Bismuth subcarbonate U.S.P.	26.0

a truly neutral solution when administered in amounts exactly equivalent to the amount of acid that is present. However, even a slight excess of the compound over the amount of acid will produce an alkaline reaction in the stomach; this effect is least with calcium and magnesium carbonates and greatest with sodium carbonate.

In the case of the buffer antacids, the situation is quite different. Owing to the nature of buffer action, it is almost impossible from a practical point of view to say how much of a given buffer substance is necessary to completely neutralize a certain amount of acid. We can, however, consider the effectiveness of buffers in lowering the acidity of a solution from pH 1 (corresponding to N/10 HCl) to about pH 2 or 3 or 4, and under these conditions we obtain the data in Table 2.

TABLE 2.—EFFECTIVENESS OF CERTAIN BUFFER ANTACIDS IN LOWERING GASTRIC ACIDITY

Compound	Grams Required to Bring 1 Liter of N/10 HCl (pH 1) to Indicated pH			
	Grams	pH	Grams	pH
Trig magnesium phosphate anhydrous	4	2	40	5
Tricalcium phosphate anhydrous	5	2	50	5
Magnesium trisilicate anhydrous	—	—	6.5	5
Sodium citrate U.S.P.	10	2	100	5
Sodium acetate U.S.P.	14	3	42	5
Mucin	65	3	—	—

FIG. 1. Influence of typical nonbuffer and buffer antacids on the pH of a solution containing N/10 HCl.

Thus for a typical buffer antacid such as sodium acetate, the addition of 14 Gm. to a liter of N/10 HCl changes the pH from 1 to 3, simply by replacing the HCl by an equivalent amount of acetic acid; and a dose three times as large, or 42 Gm., is required to lower the acidity to a point corresponding to pH 5. It is almost impossible to administer enough of this antacid to render the solution actually alkaline. Essentially the same thing is true of the other buffer antacids listed in Table 2.

The fundamental difference between buffer and nonbuffer antacids, which may be seen by comparing Tables 1 and 2, is also illustrated by Fig. 1, which shows the change in pH of a solution of N/10 HCl on the addition of increasing amounts of a nonbuffer antacid, such as sodium bicarbonate, and a buffer antacid, such as sodium acetate.

From Fig. 1 it can be seen that no significant neutralizing power is exerted by either the buffer or the nonbuffer antacid until almost the full theoretic dose is added to the solution. That is, an amount of antacid insufficient to react with all of the acid present is of little or no practical value in lowering gastric acidity. When an excess of antacid is administered, the difference between buffer and nonbuffer antacids becomes evident. In the case of nonbuffer antacids such as sodium bicarbonate and the others listed in Table 1, a slight excess over the amount of acid that is present causes a sharp rise in pH to above the neutral point and into the alkaline range. As long as the excess antacid remains in the stomach, the stomach contents will remain alkaline, and will again become acid only after sufficient HCl has been secreted to react with the amount of antacid that is present.

The equivalent dose of the buffer antacid sodium acetate does not produce a neutral or alkaline reaction in the stomach contents, but

simply brings about the replacement of the hydrochloric acid by the much weaker acetic acid, changing the pH from 1 to about 3. The further addition of even a great excess of the antacid results in the gradual lowering of acidity shown by the gradual rise in pH, in Fig. 1. It is clear that it would require a relatively enormous dose to bring about even a weak degree of alkalinity in the stomach contents.

Thus a buffer antacid does not render the stomach contents alkaline when an overdose is given, as do the nonbuffer antacids, but merely alters the pH of the stomach contents from what corresponds to a strongly acid solution to what corresponds to a weakly acid solution. If now to this buffered weakly acid solution more HCl is added, as long as an excess of the buffer antacid is present the gastric acidity will remain low (pH 3 or higher); but if sufficient HCl is added to exceed the amount of buffer antacid present, the gastric contents will once more become strongly acid (pH 2 or lower).

It has been pointed out that no antacid is of any value unless an excess is administered. From this viewpoint, the chief difference between the buffer and nonbuffer antacids is in the pH of the gastric contents after the dose. For the nonbuffer antacids of Table 1, the pH will always correspond to an alkaline solution, of greater or less alkalinity, depending upon the particular antacid that is used. For the buffer antacids the pH will be that of a weakly acid solution. The choice between the two types of antacids thus depends upon the degree of acidity or alkalinity desired in the stomach after administration.

Now let us consider for a moment some of the chemical and physical characteristics of the individual antacids, since they differ considerably in their solubility, degree of acidity or alkalinity in solution, and rate of reaction with acid. The soluble antacids include sodium carbonate, bicarbonate, citrate, and acetate, and also mucin. The others listed are insoluble but, with the exception of magnesium trisilicate, they form soluble compounds with acid. The effectiveness of an antacid will depend to a great extent upon its rate of contact with acid. It follows that a soluble antacid will react much more rapidly than an insoluble compound, but, on the other hand, an insoluble antacid may be removed from the stomach less rapidly than one that is soluble, and the latter fact appears to be of considerable significance. It is probably for this reason, for instance, that calcium carbonate is found, in clinical experience, to be one of the

most effective antacids. Even though calcium carbonate is quite insoluble in water, it reacts rapidly with acid, and the excess tends to remain in the stomach, neutralizing additional acid as it is secreted.

Magnesium trisilicate is somewhat different. It is not only insoluble but also forms the insoluble silicic acid on reacting with mineral acid. For this reason the rate of reaction with acid is extremely slow. In the laboratory, for instance, hours of stirring are required, even at body temperature, for complete reaction between magnesium trisilicate and HCl. Thus, despite an apparent superiority over other buffer antacids in requiring a smaller dose for a given pH change, magnesium trisilicate would be regarded as one of the least desirable antacids if rapid reduction of acidity were necessary.

Now just a word about an antacid that is coming into common use and that is not included in either of the tables given here. I refer to aluminum hydroxide in suspension. Different preparations of aluminum hydroxide differ markedly in their ability to react with acid, some forms of the compound not reacting at all; but a suitable preparation may be quite satisfactory as an antacid. Such preparations have the advantages of being insoluble, of reacting fairly rapidly with acid, and of not alkalinizing the gastric contents when given in excess, thus combining the virtues of both buffer and nonbuffer antacids. One such preparation obtained on the open market was found to "neutralize" ten times its volume of N/10 HCl, the pH going from an initial value of 1 to about 4 and staying at this value in the presence of excess antacid.

DR. CATTELL: Next, Dr. Travell will discuss some pharmacologic aspects of the drugs used in peptic ulcer.

DR. JANET TRAVELL: In reviewing the agents used in the treatment of peptic ulcer, one is impressed both with their number and with the variety of objectives which their use has in view.

Briefly, the therapeutic agents may be grouped in general as follows: First, there are the substances which neutralize acid. This group includes the antacid powders, gastric mucin, and proteins such as milk. A second category includes those agents, such as astringents and demulcents, that also act locally and are said to protect the surface of the ulcer. The value of such substances is not clearly established. Thirdly, there are the "antispasmodics," which reduce gastrointestinal motility. Here we place atropine, with a ques-

tion mark. In this category are certain drugs that have chiefly a direct action on muscle, such as syntropan, trasentin, the nitrites, and papaverine. There may be a fourth group which includes "acid inhibitors"—that is, substances that directly reduce the rate of secretion of gastric juice. Atropine may belong in this group, as well as oil of peppermint and the other volatile oils. It has also been postulated that there is a specific chemical regulator of acid secretion, and that peptic ulcer is the result of a deficiency of a hormone that normally inhibits the formation of acid. In a fifth group are agents which influence psychic factors; that is, sedatives such as the barbiturates. Finally, there is a miscellaneous group comprising such agents as histaminase, posterior pituitary solution, the sex hormones, and the vitamins.

In reviewing the figures for the neutralizing value of the antacids which Dr. Summerson has given you, it is well to remember that the teaspoonful rather than the gram is the measure of dosage with which the patient is familiar. The variation in bulk of these powders is considerable. For instance, the weight of a teaspoonful of sodium bicarbonate is 5.5 Gm., and therefore 1½ teaspoonfuls are required to neutralize a liter of tenth-normal hydrochloric acid. The weight of a teaspoonful of calcium carbonate is 2.5 Gm., and therefore two teaspoonfuls of this substance are required to neutralize a liter of tenth-normal hydrochloric acid. A teaspoonful of bismuth subcarbonate weighs 3.5 Gm., and since its neutralizing capacity is very low, the dose equivalent to this amount of acid would be 7½ teaspoonfuls. There are two kinds of magnesium oxide, light and heavy. The heavy is about four times as heavy as the light; the weight of a teaspoonful of the heavy powder is 2.0 Gm., and that of the light is only 0.5 Gm., so that the relative amounts necessary to neutralize a liter of tenth-normal hydrochloric acid are 1 teaspoonful of the former and 4 teaspoonfuls of the latter.

Dr. Summerson has pointed out that the chief difference between the buffers and the nonbuffers is the ultimate pH level produced in the stomach when an excess of the antacid is added. That brings us to the first problem in antacid therapy, which is: What pH represents effective control of acidity? The answer to this question depends on what the objective of antacid therapy is thought to be. If the lowering of the pH of the gastric contents has the purpose of reducing the irritant or corrosive action of hydrochloric acid, the maintenance of

a pH of about 3 or higher would represent adequate neutralization, since practically all of the free hydrochloric acid is neutralized at this pH. If the objective of therapy is the inhibition of peptic activity, it is said that the pH level must be raised considerably higher, to about 5. That is the figure that is usually given. It is known that peptic activity proceeds at its maximum rate at a pH of 1.8 to 2.4; at a pH of 4 it is reduced to 10 per cent, and at a pH of 4.4, it falls off to about 5 per cent. At a pH of 5 the activity of this enzyme almost entirely ceases, and this has been termed by Hollander the "proteolytic neutralization point." However, there are recent clinical experiments using intragastric pH determinations which show that for all practical purposes the proteolytic digestion of egg-white within the stomach ceases at a pH of about 3.5.

A second problem in the use of antacids is this: Does the degree of neutralization obtained by the various antacids within the stomach parallel their antacid potency as determined in the test tube? Can we use the latter figures as a guide to what we may expect clinically from antacid therapy? The evidence on this point seems to indicate that there is not necessarily any such parallelism. For instance, Kirsner and Palmer, in a large number of experiments on ulcer patients, determined the average reduction of acidity in aspirated samples of gastric juice, and found that 2 Gm. of calcium carbonate, which theoretically neutralizes only 250 cc. of 0.5 per cent hydrochloric acid, was more effective than doses of 16 and 30 cc. of aluminum hydroxide, which theoretically neutralize 544 and 1,207 cc., respectively. This difference in intragastric neutralizing potency may be due to the slowness of the reaction in the case of the aluminum hydroxide, which Dr. Summerston has mentioned, with consequent loss of the material from the stomach before it has had time to react. The effectiveness of a substance in neutralizing gastric acidity depends not only on the chemical neutralization equivalent but obviously on other factors, such as the rate of chemical reaction, solubility, and diffusibility, the rate of passage of the antacid from the stomach, and possibly on the degree of rebound acidity which it induces.

In general the attributes of the ideal antacid as described by Loevenhart and Crandall still hold true. The first essential is high neutralizing potency. The antacid should also be nearly neutral itself and should neutralize acid without the liberation of carbon dioxide. It should be poorly absorbed, but,

if absorbable, it should be nontoxic. Especially, it should not alter the acid-base equilibrium of the body. It seems to me that although it has certain disadvantages, the antacid that seems best to fit the description of an ideal antacid is calcium carbonate.

The fundamental difficulty in correlating in vitro and in vivo neutralizing potencies lies in the dissimilarity of the conditions which exist in the test tube and in the stomach. In the test tube, the alkali and acid are thoroughly mixed. In the stomach, layering of the contents takes place, so that it has been said that the stomach behaves "not like a churn but like a hopper." In patients receiving alkalis at stated intervals, Eyerly and Breuhhaus have compared the pH values obtained on aspirated samples with those obtained by means of a glass electrode placed in the antrum of the stomach, and they find wide discrepancies. The pH of the aspirated samples shows wider fluctuations and is usually higher than the pH within the antrum.

When one comes to the problem of evaluating antacid therapy, even greater difficulties are encountered. Are control of gastric acidity and control of symptoms synonymous? That is a question I should like to leave for discussion.

DR. CATTELL: Dr. Weintraub will now discuss some practical aspects of the management of the patient with peptic ulcer.

DR. SYDNEY WEINTRAUB: Peptic ulcer should be regarded as a local manifestation of a general constitutional disturbance in which the psychic factors play just as important a role as the somatic factors. In other words, we must treat not only the ulcer but the patient as a whole. These patients are usually of the vagotonic type, nervous, high-strung, and worrisome. It is just as important to go into their personal problems as to prescribe diets and medicine. Secondly, these people should be examined for the presence of focal infection. Although it has not been proved that focal infection is the cause of ulcer, nevertheless infected teeth, tonsils, or sinuses, or a chronically inflamed appendix or gallbladder may either prevent the healing of an ulcer or be responsible for the recurrence of the lesion.

There are two main types of treatment for ulcer. One is the bed-rest treatment, and the other is the ambulatory plan. Theoretically, every ulcer should receive the bed-rest treatment, but this is not always feasible when one is dealing with clinic patients. Definite indications for bed-rest treatment are the presence of an ulcer large in size, or evidence of bleeding,

obstruction, or threatened perforation. This last complication should be suspected when the pain becomes more severe and radiates through to the back and fails to be relieved by food and alkalis.

The bed-rest treatment follows more or less the regimen devised by Sippy. It consists essentially of hourly feedings of 90 cc. of equal parts of milk and cream from 7 A.M. to 7 P.M. Sippy also prescribed the following powders:

- I. Magnesium oxide
Sodium bicarbonate aa 0.6 Gm.
- II. Bismuth subcarbonate 0.6 Gm.
Sodium bicarbonate 1.2 to 1.8 Gm.

These powders were to be taken alternately between feedings and then continued hourly until 10 P.M. It will be noted that the patient received approximately 15 Gm. of sodium bicarbonate in fifteen hours. As a result of this, many patients developed alkalosis. This condition should be suspected when the patient develops a distaste for food, particularly for milk. He also may say that the milk tastes sour. Other symptoms of alkalosis are headache, weakness, nervous irritability, dizziness, nausea, vomiting, and aching pains in the muscles and joints. In the severe cases, prostration, mental apathy, tetany, and convulsions may develop. If alkalosis is suspected blood chlorides and carbon dioxide combining power should be determined.

We prefer to use Eusterman's modification of the Sippy powders:

- I. Calcium carbonate
Sodium bicarbonate aa 0.6 Gm.
- II. Calcium carbonate
Heavy magnesium oxide aa 0.6 Gm.

It should be noted that powder No. I contains the same amount of sodium bicarbonate as the Sippy powder No. I, and must therefore be used with the same precautions in order to avoid alkalosis. If the magnesium oxide in powder No. II proves too laxative, an equal amount of bismuth subcarbonate may be substituted.

While alkalinization is an essential part of the treatment of ulcer, it should not be continued over too long a period after the ulcer is healed. Most simple ulcers will heal in one to four weeks. Healing is indicated by the fact that the patient is clinically free of symptoms and by radiographic evidence. We must admit that we have seen very few cases of alkalosis in our clinic, and they have been very mild.

The other drugs most commonly used in the treatment of ulcer are belladonna and phenobarbital. These may be combined either in a capsule containing 15 mg. ($\frac{1}{4}$ grain) of extract of belladonna and 15 mg. ($\frac{1}{4}$ grain) of phenobarbital, or in a mixture consisting of 0.5 cc. (8 minims) of tincture of belladonna in 5 cc. of elixir of phenobarbital. This combination has both a sedative and an antispasmodic action. Even though the dose of belladonna is small, it has been observed that most patients show that the drug is effective. Many will develop symptoms of atropine saturation in a week or two.

In the ambulatory treatment, the patient receives three meals consisting of milk, cream, eggs, thoroughly cooked cereals, puréed vegetables, stewed fruits with cream, and minced chicken, with milk, malted milk, buttermilk, or cocoa given between meals and at bedtime. In choosing an alkali for the ambulatory patient, one must consider not only its effectiveness but also its palatability and cost. We use a mixture containing equal parts by weight of calcium carbonate and light magnesium oxide flavored with a little oil of peppermint. A heaping teaspoonful is given one hour after meals, at the time when the acid tide is apt to be at its height. This dose contains approximately 0.8 Gm. of calcium carbonate and 0.8 Gm. of magnesium oxide. Theoretically, calcium carbonate is probably the best single antacid, but it should be noted that many of the patients who receive it are constipated, and the addition of a magnesium salt to the calcium carbonate tends to counteract this condition and provides the most useful mixture. The night pain is controlled by the ingestion of milk or antacids.

Before leaving the subject of alkalis, one should mention aluminum hydroxide gel. We have not been able to discern that it possesses any advantages over the antacids mentioned above. On the other hand, many patients have found it to be very constipating, and some have complained of nausea.

So much for the treatment of the acute ulcer symptoms. The intake of vitamins during the first three or four weeks of treatment does not concern us, but subsequently this must be given consideration. Orange juice or grapefruit juice is allowed as dessert. The taking of fruit juices before breakfast very often produces symptoms of hyperacidity. In addition, sufficient doses of vitamin B complex are given. We also emphasize the need for complete abstinence from tobacco.

I will mention briefly some other methods of

a pH of about 3 or higher would represent adequate neutralization, since practically all of the free hydrochloric acid is neutralized at this pH. If the objective of therapy is the inhibition of peptic activity, it is said that the pH level must be raised considerably higher, to about 5. That is the figure that is usually given. It is known that peptic activity proceeds at its maximum rate at a pH of 1.8 to 2.4; at a pH of 4 it is reduced to 10 per cent, and at a pH of 4.4, it falls off to about 5 per cent. At a pH of 5 the activity of this enzyme almost entirely ceases, and this has been termed by Hollander the "proteolytic neutralization point." However, there are recent clinical experiments using intragastric pH determinations which show that for all practical purposes the proteolytic digestion of egg-white within the stomach ceases at a pH of about 3.5.

A second problem in the use of antacids is this: Does the degree of neutralization obtained by the various antacids within the stomach parallel their antacid potency as determined in the test tube? Can we use the latter figures as a guide to what we may expect clinically from antacid therapy? The evidence on this point seems to indicate that there is not necessarily any such parallelism. For instance, Kirsner and Palmer, in a large number of experiments on ulcer patients, determined the average reduction of acidity in aspirated samples of gastric juice, and found that 2 Gm. of calcium carbonate, which theoretically neutralizes only 250 cc. of 0.5 per cent hydrochloric acid, was more effective than doses of 16 and 30 cc. of aluminum hydroxide, which theoretically neutralize 544 and 1,207 cc., respectively. This difference in intragastric neutralizing potency may be due to the slowness of the reaction in the case of the aluminum hydroxide, which Dr. Summerston has mentioned, with consequent loss of the material from the stomach before it has had time to react. The effectiveness of a substance in neutralizing gastric acidity depends not only on the chemical neutralization equivalent but obviously on other factors, such as the rate of chemical reaction, solubility, and diffusibility, the rate of passage of the antacid from the stomach, and possibly on the degree of rebound acidity which it induces.

In general the attributes of the ideal antacid as described by Loevenhart and Crandall still hold true. The first essential is high neutralizing potency. The antacid should also be nearly neutral itself and should neutralize acid without the liberation of carbon dioxide. It should be poorly absorbed, but,

if absorbable, it should be nontoxic. Especially, it should not alter the acid-base equilibrium of the body. It seems to me that although it has certain disadvantages, the antacid that seems best to fit the description of an ideal antacid is calcium carbonate.

The fundamental difficulty in correlating *in vitro* and *in vivo* neutralizing potencies lies in the dissimilarity of the conditions which exist in the test tube and in the stomach. In the test tube, the alkali and acid are thoroughly mixed. In the stomach, layering of the contents takes place, so that it has been said that the stomach behaves "not like a churn but like a hopper." In patients receiving alkalis at stated intervals, Eyerly and Breuhaus have compared the pH values obtained on aspirated samples with those obtained by means of a glass electrode placed in the antrum of the stomach, and they find wide discrepancies. The pH of the aspirated samples shows wider fluctuations and is usually higher than the pH within the antrum.

When one comes to the problem of evaluating antacid therapy, even greater difficulties are encountered. Are control of gastric acidity and control of symptoms synonymous? That is a question I should like to leave for discussion.

DR. CATTELL: Dr. Weintraub will now discuss some practical aspects of the management of the patient with peptic ulcer.

DR. SYDNEY WEINTRAUB: Peptic ulcer should be regarded as a local manifestation of a general constitutional disturbance in which the psychic factors play just as important a role as the somatic factors. In other words, we must treat not only the ulcer but the patient as a whole. These patients are usually of the vagotonic type, nervous, high-strung, and worrisome. It is just as important to go into their personal problems as to prescribe diets and medicine. Secondly, these people should be examined for the presence of focal infection. Although it has not been proved that focal infection is the cause of ulcer, nevertheless infected teeth, tonsils, or sinuses, or a chronically inflamed appendix or gallbladder may either prevent the healing of an ulcer or be responsible for the recurrence of the lesion.

There are two main types of treatment for ulcer. One is the bed-rest treatment, and the other is the ambulatory plan. Theoretically, every ulcer should receive the bed-rest treatment, but this is not always feasible when one is dealing with clinic patients. Definite indications for bed-rest treatment are the presence of an ulcer large in size, or evidence of bleeding,

must help patients to readjust if we expect them to do well.

DR. WHEELER: Suppose that a patient with severe ulcer symptoms has been put to bed, has received the Sippy regimen, barbiturates, belladonna, and alkalis, and after a period of time becomes free of symptoms, how soon, Dr. Weintraub, do you start giving other foods besides milk and cream?

DR. WEINTRAUB: Usually the diet of milk and cream is continued for three or four days, and then the patient is allowed supplementary feedings. These are given three times a day and at the start consist of 6 ounces of creamed puréed vegetable soup, junket, custard and puddings, puréed vegetables, etc. Then after eight or ten days the supplementary feedings are increased to five or six a day, and that routine is usually kept up for about two months. Then gradually the meat of chicken, fish, steaks, and chops and other foods are added, until finally the patient is receiving a full diet, with the exception, of course, of highly seasoned foods.

The question also arises as to how long one should continue the use of alkaline powders. There are some physicians who continue them after each meal for months, or even a year, but I usually discontinue them after three months if there are no symptoms, and advise the patient to keep a supply of the powders on hand and to take a dose if he has any indigestion or any symptoms of hyperacidity.

DR. CATTELL: Does that accord with your practice, Dr. Heffner?

DR. HEFFNER: Perhaps some of us go a little farther than that, particularly in duodenal ulcer. We usually insist that the patient remain on fairly strict management for six to twelve months, regardless of how soon the symptoms disappear after the regimen is begun. Tobacco and alcohol are interdicted during this period. In many cases the judicious use of sedatives is just as important as the use of alkalis. It is well to inform all patients with duodenal ulcer at the outset of treatment that a bland, nonirritating type of diet should be followed permanently.

DR. CATTELL: One topic which has not received attention today is the place of atropine in ulcer therapy. We should like to hear from Dr. Holland and from Dr. Gold on that subject.

DR. ARTHUR L. HOLLAND: Atropine and belladonna stand out as the principal agents we employ as antispasmodics. The pharmacologists do not always agree with us here. They say that the ordinary amounts that can

be given safely do not produce any effect, or rather not enough effect, to be worth while. I agree that spasm is not affected very much by belladonna or atropine, but these agents seem to establish a better balance between the vagus and the sympathetics, which has something to do with quieting and regulating the peristalsis of the gastrointestinal canal. Again we must remember that since many of the data have been gathered through animal experimentation, and since the various species of experimental animals are known to differ in their reactions to drugs, the results may not apply clinically.

But in atropine and belladonna we have friends, despite the pharmacologists. I have given these drugs routinely for a great many years. It is curious how often, when we have discontinued atropine for one reason or another, the patient has called up and asked if we would not please go on with "that laxative pill"—evidently missing the effect of the atropine. But, as I have said, I have not seen atropine afford any definite relief from spasm of the true sphincters, as of the pylorus or the cardia. I have never been able to observe fluoroscopically that atropine relieved such spasm. On the other hand, when one is unable to fill out the duodenal bulb because of severe pylorospasm, a whiff of amyl nitrite will temporarily relieve the spasm. A very simple preparation—spirit of peppermint—will also sometimes secure relaxation.

DR. HARRY GOLD: First let me mention a practical point. Atropine is often given in the form of tincture of belladonna in doses of the order of 5 minims, two or three times a day. Sometimes this is prescribed as "5 drops." It is well to remember that in the case of alcoholic solutions 5 drops and 5 minims are not the same: there are about $2\frac{1}{2}$ drops in 1 minim of the tincture. I wonder what the practice is in this hospital?

DR. WHEELER: Many medicine droppers such as those we have on our wards, deliver as many as 50 drops of tincture of belladonna to the cubic centimeter. On this basis an initial dose of 10 drops three times a day, such as is often prescribed, hardly seems sufficient. The routine procedure on the Medical Service is to measure the dose in a 1-cc. graduate.

We usually prescribe tincture of belladonna in a dose of 0.3 cc. three times a day, and increase the dose by 0.1 cc. three times a day until dryness of the mouth or blurring of near vision appears, at which point each of the three daily doses is reduced by 0.1 or 0.2 cc. This means that we start with a dose of about 0.1 mg. of

treatment that are in vogue: first, parenteral injections of lipoproteins, histidine, and non-specific proteins. In our experience these substances have not proved beneficial. Secondly, there is gastric mucin. We do not often use this because its taste and odor render it unpalatable and very few patients can tolerate it. The average dose is 60 cc. taken in chocolate malted milk three times a day. Occasionally it will relieve symptoms when the ordinary alkaline therapy has failed. One should be very cautious, however, in evaluating the results of a particular type of therapy, since statistical analyses have shown that no matter what type of treatment is employed, 80 per cent of the patients are still symptom-free at the end of one year, 60 per cent after two years, 50 per cent after three years, 30 per cent after four years, and 20 per cent after five years. Emery and Monroe, at the Peter Bent Brigham Hospital, have shown, furthermore, that essentially the same results are obtained when no treatment at all is given.

The question frequently arises whether the medical treatment for ulcer is designed mainly for the relief of symptoms or whether it effects a cure. One may state that no form of treatment, either medical or surgical, can guarantee a permanent cure. However, as a rule the symptoms are an excellent indication of the status of the ulcer. When the pain disappears, it can be assumed that the ulcer is healing. The best evidence of healing, however, can be obtained by a radiographic examination and includes the disappearance of the niche, the absence of spasm, and diminution of peristalsis. The control of hypersecretion is a matter of importance. A question which has been raised is whether the control of symptoms and the control of gastric acidity are correlated. This should be answered in the affirmative. As a rule the prognosis is poor if the gastric acidity remains high in spite of treatment. Occasionally an ulcer will heal temporarily in spite of the presence of high gastric acidity, but a recurrence of the lesion is very likely to occur.

DR. CATTELL: The meeting is now open for discussion.

DR. TRAVELL: I should like to raise the question as to whether the beneficial effects of milk depend upon its antacid properties or on some other factors. I think Dr. Summerson has some interesting figures on the neutralization equivalents of milk.

DR. SUMMERSON: If milk is added to tenth-normal hydrochloric acid, it acts as a buffer, but it is not nearly so effective as the common

antacids on the dry basis. It takes about one volume of milk to influence appreciably the acidity of one volume of ordinary gastric juice. For a liter of tenth-normal hydrochloric acid, for instance, one would have to give a liter or more of milk to bring the pH from 1 to about 2.5. Thus the volume of milk required is considerable.

DR. TRAVELL: Kirsner and Palmer have also shown in their curves of gastric acidity in ulcer patients that the neutralizing power of milk within the stomach is not high.

DR. C. H. WHEELER: Although it is at variance with what has been said about the chemical value of milk as an antacid, my impression is that large numbers of patients with ulcer obtain complete symptomatic relief from the use of milk and cream every hour without the use of an alkaline powder.

I should like to ask Dr. Weintraub and the other clinicians whether they have also observed that.

DR. WEINTRAUB: It is my impression that this is so. Milk relieves symptoms and seems to act just as the alkaline powders do.

DR. TRAVELL: It seems that we have no adequate explanation for the symptomatic relief afforded by the use of milk.

DR. CATTELL: Do you wish to comment, Dr. Heffner?

DR. REID R. HEFFNER: So far, most of the discussion has centered around treatment of the acute symptoms of ulcer, which is only a part of the management of this important diathesis or disease. Duodenal ulcer is the most common cause of chronic, recurring dyspepsia. Oftentimes the chronicity of this disorder is lost sight of, and that, in my opinion, is responsible for many of the complications. We have all heard the familiar saying, "Once an ulcer always an ulcer," which is not quite correct, but whoever said, "Once an ulcer always potentially an ulcer," more truthfully expressed it. Patients with duodenal ulcer should have the same kind of explicit advice relative to their management as diabetic or cardiac patients receive concerning their care. Ulcer patients should be taught how to avoid exacerbations of symptoms in order to eliminate complications.

There is no routine way to manage patients with peptic ulcer. Whether it is overwork, worry, nervous tension, the use of tobacco or alcohol, or improper food, the result of the indiscretion is usually the same. These factors and many others contribute to the chronicity of ulcer, and they are the problems that we

perhaps to make a distinction between the effects on spasm or motility and the effects on secretion. The fact that spasm in response to vagal stimulation cannot be abolished by large doses of atropine is well known, but there is a great deal of evidence to show that atropine reduces the volume of gastric secretion. Kirsner and Palmer have some clinical experiments that demonstrate this effect. Using doses of 1 mg. of atropine sulfate four times a day by mouth, they found that the total volume of gastric fluid secreted was reduced about 40 per cent, and also that the neutralizing potency of the antacids was greatly enhanced by these doses of atropine, probably owing to the smaller quantity of gastric juice presented for neutralization. Atropine, however, does not alter the pH so long as any gastric juice is being secreted.

DR. GOLD: Mind you, these doses are about four times as large as the doses recommended in this hospital. One can't give such doses without causing considerable discomfort. And what good are they?

DR. H. B. RICHARDSON: I understand that there is agreement as to the effect of atropine on spasm. When there is definite spasm of the cardia or pylorus, it cannot be relaxed by atropine. That is Dr. Holland's statement, as well as Dr. Gold's.

DR. HOLLAND: Yes. In line with Dr. Gold's statement, that to be of service atropine or belladonna should be used in much larger doses than is usual, I would report that I have recently been using atropine sulfate intravenously in doses of $\frac{1}{100}$ of a grain once or twice a day, and after two or three days reducing the amount to $\frac{1}{100}$ of a grain. This, of course, would not be indicated in peptic ulcer, but where there is prolonged and painful spasm in the gastrointestinal tube beyond the stomach.

One patient, who had been cured of morphine addiction that had resulted from a series of abdominal operations, developed an extremely severe colic. Because of complicated mechanical difficulties Dr. Edward Zabriskie suggested and administered the atropine in this manner to this patient, with quite remarkable results. For some strange reason, the throat dryness and visual symptoms were lacking even with this large dose, and the pain was relieved at once without any other form of sedation. I am not sure that all patients would tolerate atropine given in this manner, but it should be thought of particularly when morphine, or narcotics of that sort, are contraindicated.

Summary

DR. TRAVELL: The medical management of peptic ulcer presents many difficulties in the way of evaluation of therapy. Such evaluation is based chiefly on the subjective appraisal of the patient, on the determination of gastric acidity, and on changes in intestinal motility, none of which have been measured with precision. In particular, it has recently been shown that there are wide discrepancies between the pH values as determined on aspirated samples of gastric juice and as determined simultaneously *in situ* within the antrum of the stomach. Healing of the ulcer may usually be secured by a plan of treatment which combines rest in bed, frequent feedings of soft food, administration of antacids, and possibly the use of atropine. Ambulatory treatment is theoretically undesirable. Bed rest is always indicated in the presence of bleeding, obstruction, impending perforation, or an ulcer large in size. Many factors, especially psychogenic ones, are involved in the prevention of recurrence of the ulcer.

The confusion which exists as to the relative merits of certain antacids may be clarified to a great extent by the following considerations: Antacids are fundamentally of two types, non-buffers and buffers. These are alike in that no significant neutralizing power is exerted until the full theoretic neutralizing dose is added, and therefore these substances are useful only when added in excess. They differ in several respects: When added in the exact equivalent of the amount of acid present, the nonbuffer antacids yield a neutral solution, the buffers a moderately acid solution. When added in excess, the nonbuffers yield an alkaline solution, and the buffers a moderately acid solution, so that in the case of the buffers one can greatly "over-run" without disturbing the normal pH range of the gastric juice. When the pH has been raised, in the case of the non-buffers it requires a relatively small amount of additional hydrochloric acid to bring the pH back to a level of 1 to 2, whereas in the case of the buffers it may require a very large amount of acid to lower the pH to this level. The buffers thus seem to possess a number of theoretic advantages over the nonbuffers. The clinical efficacy of an antacid, however, is determined not solely by its acid-neutralizing potency, but also by other factors, especially its physical characteristics. For instance, the solubility of the antacid influences both the rate of reaction with acid and the rate of removal of the substance from the stomach;

atropine three times a day, which is gradually increased until, in most instances, the patient is receiving about 0.4 mg. of atropine three times a day.

Do you think that dosage is effective?

DR. GOLD: Maybe it is a good idea to introduce a little heresy into the record in regard to atropine. I should like to challenge the view that a dose of 1 cc. of tincture of belladonna, which represents a total of about 0.3 mg. ($\frac{1}{200}$ grain) of atropine, three times daily exerts a significant effect on peptic ulcer patients. There are three facts that need to be borne in mind. The first is that doses of atropine which in animals block the vagus to the heart, and which block the secretory parasympathetic fibers to the salivary glands, have practically no effect in abolishing movements of the intestinal tract. If the vagus is stimulated after such large doses of atropine, the intestinal tract still continues to respond. If one protests that these are experiments on animals, there remains the second fact to puzzle us—namely, the results of experiments directly on man, in which very large doses of atropine are given ($\frac{1}{25}$ of a grain by intravenous injection) and then an analysis is made of the gastric contents. When that is done, one finds that these patients are still secreting gastric juice and hydrochloric acid in abundance, especially after a meal. Furthermore, atropine does not relax the pylorospasm to facilitate examination by x-ray, and if the stomach happens to be cut almost in two by an hour-glass constriction, large doses also fail to relax that spasm.

Then we have the third fact, Dr. Holland's experience and the experience of others—namely, that patients seem to do better when they receive these small doses of atropine. What are these doses doing if one cannot demonstrate any significant effect on the stomach? I know that most gastroenterologists say that patients feel better when they receive such doses of atropine, but there is a way to find out the meaning of that observation, and that is to give them a placebo that has the proper taste or flavor. That kind of a test has never been made. I am convinced that these doses of tincture of belladonna do nothing to the gastrointestinal tract that is important in the treatment of peptic ulcer.

Of course, 1 cc. of tincture of belladonna will cause a great many symptoms, but I think we ought not to assume that the dryness of the mouth and the pupillary effects imply changes in the gastrointestinal tract. The gastrointestinal tract is notoriously resistant to the action

of atropine. The duration of atropine action is also of interest in this connection. In the gastrointestinal tract the effect of large doses lasts about half an hour to three hours, whereas the mouth and eye effects last for days. Hence when one stops giving the drug because the head symptoms have appeared, in the belief that these head symptoms indicate also gastrointestinal effects, I think one is misled.

DR. JOHN DEITRICK: Is there no accumulation of the drug in the body which might account for an effect on the stomach after ten days or two weeks of administration of such small doses?

DR. GOLD: There is. But that applies to other parts of the body as well. As a matter of fact, the accumulation has a greater effect on the head symptoms than on the gastrointestinal symptoms, by reason of the fact that the duration of the effects is longer in the head than in the gastrointestinal tract.

DR. DEITRICK: I have seen patients develop atropine symptoms after a week or ten days on a daily dose of 10 drops of tincture of belladonna. There is no argument about that; the pupillary reaction is absent and the mouth is dry. I wonder whether there is not also an accumulated effect on the gastrointestinal tract.

DR. GOLD: We simply must separate the head from the gastrointestinal tract in talking about atropine. Those are two separate problems. Marked effects in one region do not indicate similar effects in the other.

DR. CATTELL: From the pharmacologic standpoint I think that distinction is extremely important because of the high threshold of the gastrointestinal tract to atropine. Furthermore, the possibility of accumulation would really be eliminated by the fact that excessive salivary effects and eye effects are usually not apparent, owing to the way in which the drug is given, so certainly there would be an insufficient amount of it to affect the gastrointestinal tract, which has a higher threshold.

DR. DEITRICK: I would not accept that. I think we ought to have some direct proof of the presence or absence of an effect on the motility of the stomach.

DR. GOLD: There is this evidence: If one gives a milligram of atropine by intravenous injection, one obtains a reduction of gastric secretion that lasts three hours, whereas the dilatation of the pupil produced by that dose may last three days.

DR. TRAVELL: When we speak of the high threshold to atropine effects, I think we have

Medical News

Naval Officer Procurement

FROM the Office of Naval Officer Procurement, 33 Pine Street, New York City, has come the following announcement:

"Many physicians interested in applying for commissions in the Naval Reserve have made inquiries relating to their status under the recent Executive Order on Manpower. This Executive Order applied only to personnel wishing to volunteer as an enlisted man and not to those eligible for volunteering as an officer. Applications of physicians are desired for existing vacancies in the ranks of Lieutenant (junior grade), Lieutenant, and Lieutenant-Commander. Physicians who have registered under the Selective Service Act and anticipate applying for commission in the Naval Reserve should know that

following making an application it takes two to three months for the commission to be issued. The Director of Naval Procurement is not permitted to request deferment of induction by the Selective Service Board pending consideration of a physician's application for a commission.

"Physical examinations of applicants may be had either at this office; the Branch Office in Buffalo; Marine Recruiting Station, Syracuse; Navy Recruiting Station, Albany; Navy Recruiting Station, New Haven; or by Lieutenant Commander G. P. Berry, M.C., U.S.N.R. Strong Memorial Hospital, Rochester."

Senior Medical Officer

County News

Albany County

The annual election of officers of the county medical society took place at 8:30 p.m. in the auditorium of the Albany Pharmacy College on December 9. Dr. John J. Phelan, retiring president, presided.

Nominations were as follows: president, Dr. Morgan O. Barrett; vice-president, Dr. John B. Horner; secretary, Dr. Homer L. Nelms; treasurer, Dr. Frances E. Vosburgh; historian, Dr. Emerson C. Kelly. Nomination usually is tantamount to election.*

* * *

At the November meeting of the county society Dr. W. Brandon Macomber spoke on "Principles of Plastic Surgery and Their Application."

Broome County

At the meeting of the county society held in the Binghamton Club on December 8 the Rev. Earle F. Anable, assistant pastor of St. Thomas Aquinas Church, spoke on "The Philosophy of Humor." A colored movie was shown through the courtesy of Agfa Ansco, according to a statement by Dr. Frank M. Dyer, public relations chairman.

The officers of 1943 were elected and will be published in a subsequent issue of the JOURNAL. The wives of the members of the society were invited to the dinner meeting and the wives of those doctors absent in military service were guests of the society.

The retiring president is Dr. Elton R. Dickson.*

* * *

According to the *Endicott Bulletin*, December 3:

A month's practice of handling emergency cases through Ideal Hospital has received praise from Robert T. Johnson, hospital superintendent.

Under the new setup, caused by shortage of doctors, persons needing emergency treatment

are asked to contact their regular physicians. If the physicians called are not available, persons then may call Ideal Hospital where they will receive the name and telephone number of a doctor who is prepared to answer such calls. [See Broome County, December 15 issue.]

"Majority of Greater Endicott doctors, through the Broome County Medical Society, have agreed to serve under the new plan. Each doctor serves a regular period, during which time he is available for all emergency calls."

Cattaraugus County

Dr. Theodore J. Holmlund, who has practiced general medicine and surgery in Cattaraugus for the last twelve years, has opened an office in the Physicians Building in Jamestown according to the *Jamestown Post-Journal*, November 25.

"Dr. and Mrs. Holmlund, and sons, James, 7, and David, 5, will reside at 101 Ellis Avenue. . . .

"Dr. Holmlund is a past-president of the Cattaraugus Medical Society.

"Dr. Holmlund tried for a commission in the Army of the United States in June, but his application was rejected, due to a nonincapacitating disability."

Dutchess County

A regular meeting of the county medical society was held on December 9 at the Golf House, Hudson River State Hospital, Poughkeepsie. A talking film from the Lahey Clinic on the subject of peptic ulcer was shown, after which there was a discussion by Drs. Scott L. Smith and R. H. Breed.

At the regular November meeting Dr. Achsa M. Bean, Major, Royal Army Medical Corps, spoke on "Civilian Military Medicine in Great Britain Today."

Dr. Bean spoke informally of her experiences in London, which were extremely interesting. Her talk is printed in the *Dutchess County Caduceus* and we wish that we had space to reprint it here. She began:

"As you probably know, Great Britain asked over two years ago for a thousand American

thus magnesium trisilicate, a theoretically satisfactory buffer, combines with acid so slowly that practically all of it may leave the stomach before any significant neutralization occurs. Calcium carbonate has probably proved to be the most effective single antacid. In patients who are constipated, a mixture of calcium carbonate and magnesium oxide may be more satisfactory than calcium carbonate alone.

The role of small doses of atropine for the relief of the symptoms of peptic ulcer is another controversial topic. Whether the subjective improvement which patients describe after the oral administration of a total daily dose of 3 cc. or less of tincture of belladonna (equivalent to about 1 mg. of atropine) is in fact due to the atropine remains an open question. It is generally believed that these

doses have some antispasmodic action, but the difficulty is that in careful experiments in both animals and man much larger doses of atropine fail significantly to relax spasm of the sphincters or to influence gastric motility. The value of atropine in reducing gastric secretion is also in dispute. There seems to be no doubt that although the pH of the gastric juice secreted after atropine is not altered, the amount of gastric juice can be diminished by atropine in man, but the experiments in which this is demonstrated involve doses of atropine that are much larger than those commonly used in the treatment of peptic ulcer. It remains to be demonstrated whether the latter doses cause a reduction in the volume of gastric juice secreted, and hence a reduction in the total amount of acid presented for neutralization by food and alkalis.

PROMOTE INSURANCE OR BE A HIRED MAN

Before long it will become evident to every doctor, as it is clearly seen now by a few, that the majority of our citizens of the next decade will meet the cost of medical care by some new plan.

No, the die is not cast. A system of medical service through a federal and state bureaucracy is not inevitable, as some of the defeatists see it.

Out of the present flux of our social relations and economic conditions several developments are possible. Only one development promises well for the man or woman who has dedicated his life to the practice of medicine.

There is a serious effort being made to extend hospital insurance to include the services of staff doctors as incident to hospital services. The Insurance Law specifically prohibits one corporation from furnishing both hospital and medical coverage. At the present time, the Associated Hospital Service of New York has promoted the organization of a corporation, through which affiliate it proposes to write a policy which completely circumvents the intent and purpose of the legislators.

Such a bill as the one introduced in the last Legislature by Mr. Hampton would give the hospitals legal right to hire doctors and sell their services to the public through the contracts of the Associated Hospital Service. Some of our Volunteer Hospital Administrators are not congenially disposed to this idea. Circumstances may force them into unwilling participation.

If no solution of the problem of payment for medical care is provided for the average man and his family by the doctors, we may expect the national and state legislatures to extend the Social Security Law to provide such relief. In this event all doctors are destined to become hired men to the great medical bureaucracy. The license to practice medicine is not a "property right." Here in New York State it will be a simple procedure to amend the Education Law with a provision that only those physicians who sign with the State System of Insurance will be continued on the roster at the time for annual reregistration.

We still have five months in which to promote enrollment of subscribers in the Medical Expense Fund to a sufficient number to assure the authorities that this method will be developed to a successful solution of the problem of meeting the cost of modern medical care.

Every doctor engaged in medical practice should be a Professional Member of the Fund.

Every doctor who is a Professional Member has among his clientele a number of persons and families who will subscribe to this voluntary insurance if the doctor merely advises them to do so.

Every doctor knows intimately at least one employer of a group of persons who, upon his urging, will promote the enrollment of those employees as Subscriber Members of the Fund.

—*Bull. Med. Soc. County of Kings*

"A good home or school uses a minimum of compulsion and a maximum of persuasion, and a church has no compulsion at all at its disposal, only persuasion to rely upon. . . yet age after

age, while empires rise and fall, these three go on —homes, schools, churches—the major builders of all the real goodness that mankind has."—*Harry Emerson Fosdick*

can invasion, friends here believed Lieut. Vickers might have been in the thick of the fighting.

"I am somewhere on the African coast—just recovering from a few days of work," he wrote.

"The phrase indicated he may have cared for casualties resulting from the invasion."

Livingston County

Dr. Charles T. Mann of Caledonia, is acting as assistant to Dr. Homer T. Bull until Dr. Bull is called for service, when Dr. Mann will take over the office practice.

Dr. Mann studied at Strong Memorial Hospital and interned at the Flower Hospital in New York. Since July 1 he has been resident physician at Mary McClellan Hospital in Cambridge. Dr. and Mrs. Mann will make their home in Genesee.*

. . .

The *Dansville Express*, December 3, said that "Dr. Simon King was appointed Town Health Officer of North Dansville, at a recent monthly meeting of the Town Board, succeeding Dr. Alden J. Townsend, resigned, who has entered military service. Dr. King will complete the unexpired term of Dr. Townsend or serve until his return."

Monroe County

Dr. Fred W. Stewart of the Memorial Hospital in New York City spoke at the regular meeting of the Rochester Academy of Medicine, on December 1, on "Chronic Atrophic Gastritis and Gastric Cancer," according to the *Bulletin*.

The work at the Memorial Hospital on the relationship between diet, diet deficiencies, gastritis, and the production of cancer is reported to be very interesting. It is a privilege to hear Dr. Stewart.

At the January meeting a round-table discussion on "Tetanus" is to be presented. Later in the season "Poliomyelitis" and the Sister Kenny treatment will be discussed.

. . .

The annual meeting of the county society was held on December 15. The officers elected at this meeting will be published in a later issue of the *JOURNAL*.

Dr. George W. Cottis, president, Medical Society of the State of New York, was the guest speaker at the meeting.

. . .

"Two Months in England" is the subject of an interesting article in the November *Bulletin* and its author is Dr. William A. Sawyer. Speaking of the English people he says: "They have become quite fatalistic. They go about their life believing everything will be all right until the bomb with their name on it comes along. There seems to be no doubt in their minds as to the final outcome and they are most appreciative of our partnership with them. If they do not show the same hectic effort some of our people display, it is because they have been at it a couple of years and have settled themselves for a long, steady pull. To them it is a marathon race instead of a hundred-yard dash."

New York County

The following officers were elected at the annual meeting held on November 23:

President-Elect..	Conrad Berens, M.D.
First Vice-President.....	Francis N. Kimball, M.D.
Second Vice-President.....	Roy B. Henline, M.D.
Secretary.....	B. Wallace Hamilton, M.D.
Assistant Secretary.....	Beverly C. Smith, M.D.
Treasurer.....	Fenwick Beekman, M.D.
Assistant Treasurer.....	John Carroll, M.D.
Censors (for three years)...	Harold B. Davidson, M.D. Howard C. Taylor, Jr., M.D.
Chairman, Com. on Legislation	John B. Lauricella, M.D.

The interesting item below was recently printed in the *Journal* of the New York County Society.

NEW YORK PHYSICIANS EDIT "DAILY SPAEF"

New York physicians are prominent on the staff of the *Daily Spaef*, service newspaper of the South Pacific American Expeditionary forces. Lieutenant-Commander Albert S. Hyman is editor-in-chief and the editorial board includes Lieutenant-Commander David I. Arbuse, Lionel H. Auster, Hammond Moody, George W. Cramp, and Henry H. Kessler.

These physicians are part of an advance naval base, with a large staff of specialists and hospital corpsmen, in the Southern Pacific. Commander Hyman is medical executive officer and chief of medicine of the outfit; George W. Cramp, of Methodist Hospital, Brooklyn, is chief of x-ray; Hammond Moody, of French Hospital,

doctors. At that time, they wouldn't have any talk of women. They must be men. I got a notice with the first group because I have a strange first name (Achsa), and it led into complications in Great Britain as well as over here. But they wouldn't take women then. A little later—I want you to appreciate this story thoroughly—they looked for the thousand men. They didn't get them. They got some. When I got to Great Britain, there were already twenty-eight American men in civilian capacities and a fair number in the Royal Army Medical Corps. But when they failed to get a thousand men, the British Red Cross said, "Well, we would like to get at least ten women because we couldn't get a thousand men."

"So we went to England. There are so many things one can tell. It was a very wonderful year for me. But I thought of the things which might interest you most, the things in reference to how civilian and military medicine were organized, what happened to the doctors when war came and what went on. We were immediately assigned to the Emergency Medical Service, and I can tell you most about the London area where for five months I worked in a civilian hospital. . . ."

Erie County

Dr. Harold F. R. Brown, first vice-president, was nominated without opposition on November, 24 to succeed Dr. Harvey P. Hoffman as president of the Medical Society of the County of Erie.

Others nominated at a meeting in the Hotel Statler in Buffalo are: first vice-president, Dr. John D. Naples; second vice-president, Dr. Patrick H. J. Buckley; treasurer (for a second term), Dr. Ralph M. De Graff; secretary (for a 14th term), Dr. Louise W. Beamis-Hood.

Members of the board of censors (five to be chosen), Dr. Francis E. Fronczak, Dr. Charles W. Bethune, Dr. Eugene M. Sullivan, Dr. Elmer T. McGroder, Dr. John C. Brady; delegates to the State Society (eight to be elected), Dr. Joseph C. O'Gorman, Dr. Alfred H. Noehren, Dr. Brady, Dr. Harold M. Johnson, Dr. Thurber Le Win, Dr. Norman C. Bender, Dr. Mary J. Kazmierczak, Dr. John T. Donovan.

These were nominated as chairmen of standing committees: Dr. Edmund A. Mackey, legislation; Dr. John W. Kohl, public health; Dr. Porter A. Steele, economics; Dr. Arthur F. Glaeser, membership.

A proposed amendment restricting membership to citizens was rejected by a narrow margin. At present physicians with first naturalization papers are eligible.*

. . . .

A special meeting to hear Dr. Winthrop M. Phelps, of Baltimore, talk on "The Treatment of Cerebral Palsies" was held at Children's Hospital under the auspices of its medical staff on December 2. The meeting was open to the entire medical profession.

Dr. Phelps, medical director of the Children's Rehabilitation Institute, Baltimore, is recognized as the outstanding authority in the United States on cerebral palsy—the conditions

of children born with physical defects. He spent the day at the Children's Hospital, reviewing the work of its cerebral palsy clinic established a year ago.

The meeting is part of the Children's Hospital fiftieth anniversary observance.*

Essex County

From the *Ticonderoga Sentinel*, December 3, the following was clipped:

"On Tuesday evening, December 1, a celebration was held in the Memorial Hall auditorium in Mineville in honor of Dr. T. J. Cummins, who on that date completed twenty-five years of service in the Town of Moriah.

An illuminated parchment scroll was presented to Dr. Cummins, bearing the following inscription:

1917-1942

THE CHARACTER AND WORTH
OF A MAN IS MEASURED BY
THE LOVE, LOYALTY AND
CONFIDENCE OF HIS FELLOW
MEN. THIS SCROLL IS IN-
SCRIBED TO SHOW OUR DEEP-
EST APPRECIATION TO
THOMAS JOSEPH CUMMINS, M.D.
FOR TWENTY-FIVE YEARS OF
DEVOTED AND UNTINTED
SERVICE TO THE COMMU-
NITY . . . AS AN EMINENT PHY-
SICIAN, A SKILLED SURGEON,
AND AN EXEMPLARY CITIZEN.

FROM
THE PEOPLE OF THE TOWN
OF MORIAH
HE LIVES TO SERVE

"In addition to this scroll, various other gifts included a complete desk and desk set and a \$1,000 War Savings Bond. Mr. J. R. Linney served as master of ceremonies, and introduced the following speakers: The Reverends A. C. Kenny, H. Smith, and S. J. Wojciechowski. The presentation was made by Mr. George C. Foote.

"A bouquet of flowers was also presented to Mrs. Cummins.

"Funds for this occasion were contributed by the residents of the Town of Moriah."

Genesee County

Dr. Ward B. Manchester, of Batavia, was named president of the county medical society to succeed Dr. Raymond L. Warn, of Oakfield, at a meeting at the Batavia Club on December 3. Dr. I. A. Cole, of Batavia, was chosen vice-president, and Dr. Peter J. Di Natale was renamed secretary and treasurer.

Dr. Herman E. Pearse, of Strong Memorial Hospital, Rochester, spoke on "Biliary Tract Diseases, Their Diagnosis and Treatment."*

Herkimer County

"Lieut. H. Dan Vickers, U.S.N., past-president of the Herkimer County Medical Society, is back in the country after serving in the North African campaign, it was learned today," said the *Herkimer Telegram* on November 30.

"The former Little Falls doctor has joined his wife, the former Frances Steel, of Utica, at Roanoke, Virginia.

"In a letter received this weekend by Mannie Feldman, Lieut. Vickers told of serving on board a ship off the African coast on Armistice day.

"While the letter did not mention the Afri-

* Asterisk indicates item is from local newspaper.

treasurer, I. N. Peterson, M.D.; delegate, C. S. Johnson, M.D.; alternate, F. Shaw, M.D.; censors, Drs. F. A. Carpenter, F. H. Spencer, and J. Jakes.

Dr. Johnson discussed the available courses for Postgraduate Education.

There was no unfinished business.

A letter from Dr. Mitchell was read and the president appointed Dr. Moulton to act as chairman of the School Health Service Committee and Dr. Hartnagle as chairman of the Tuberculosis Committee as subcommittee under the Public Health Committee.

Dr. Hugh Gregory, superintendent of Binghamton State Hospital, spoke to the society on "Problems in Psychiatry in Wartime." A round-table discussion with questions and answers was then held.—*I. N. Peterson, M.D., Secretary.*

Washington County

The *Glens Falls Times* of December 3 said that "Dr. Silas J. Banker was in Albany recently to attend the meeting of the county secretaries of the New York State Medical Association. In the absence of Dr. D. M. Vickers, of Cambridge, Dr. Banker represented Washington County at the meeting. Dr. Banker was secretary of the Washington County Medical Society for thirty years."

Westchester County

In the December issue of the *Westchester*

Medical Bulletin the following announcement was made:

"OUR OBLIGATION TO OUR COLLEAGUES IN THE SERVICE"

If you are a member of the society, you will find enclosed with this *Bulletin* a poster entitled "Our Obligation" which you are requested to sign and display in your office or waiting room. This is one of a number of steps taken or anticipated by the county medical society in an effort to preserve, as far as is practicable, the clientele and professional contacts of our colleagues in service.

The poster merely expresses to those of your patients who formerly were attended by a doctor now in service the hope that they will resume their former relationship with your colleague when he returns from military service. It is hoped that you will cooperate in this effort by displaying this poster.

. . .

Also in the *Bulletin* we found this interesting item:

"Major Robert Lateiner of the Medical Corps of the U.S. Army Air Forces, formerly of New Rochelle, is the author of a thrilling story of the evacuation by air of the European residents of Burma during the occupation of that country by the Japanese. The article entitled, "The Heroism of Burma's Dunkirk," appeared first in *Cosmopolitan* of November, 1942, and was reprinted the same month in the *Reader's Digest* for November, 1942. Major Lateiner has been in active service since November, 1940."

Deaths of New York State Physicians

is chief of genitourinary surgery; David I. Arbuse, of Mount Sinai Hospital, is chief of neuropsychiatry, and Henry H. Kessler, of Newark Beth Israel Hospital, is chief of orthopaedic surgery. The work of this outfit consists of handling the casualties occurring in the South Pacific area of action. Results have been extraordinarily good and compare favorably with the figures of any hospital in New York.

The *Daily Spaef* is published in a tent, often in the midst of naval activities. Its editors, and indeed all of the members of the outfit, are eager for mail from home and for the *Journal*, which is their "only contact" with their former life as "just plain civilian doctors."

Dr. Bernard Sachs, past-president of the New York Academy of Medicine, and one of the world's leaders in neurology, was honored in November at a special ceremony at the Mount Sinai Hospital in tribute to his "sixty years of participation in the progress of medicine." Two hundred neurologists and psychiatrists attended the ceremony, at which Dr. Foster Kennedy, chief of the Neurological Service at Bellevue Hospital, presided.*

The *World-Telegram*, New York City, recently carried a special feature story on Dr. Howard Lilienthal—"brisk and advanced at 81," the reporter described him. He recalled in the interview the hearty old days when he saw a celebrated surgeon sharpen a scalpel by stropping it on his shoe in the midst of a critical operation and often saw another hold the knife in his teeth between cuts, as well as other interesting incidents in his early years of practicing medicine.

Dr. Lilienthal was a surgeon on the staff of Mt. Sinai Hospital for forty-eight years. The hospital is now having its 90th anniversary exhibit and planning a celebration in honor of its 500,000th patient.

Queens County

Medical society officers elected on November 24 to serve during 1943 are as follows: president-elect, W. Guernsey Frey, Jr., M.D.; secretary, Ezra A. Wolff, M.D.; assistant secretary, Leo Goldberg, M.D.; treasurer, John J. Sheehy, M.D.; assistant treasurer, Arthur A. Fischl, M.D.; historian, Joseph S. Thomas, M.D.; directing librarian, Alfred Angrist, M.D.; assistant directing librarian, Sol Axelrad, M.D.; trustees, Goodwin A. Distler, M.D., James R. Reuling, M.D., and Joseph Wrana, M.D.; censors (Third District)—Daniel Swan, M.D., (Fourth District)—Meyerson Coe, M.D., (Fifth District)—Louis Sarrow, M.D., (at large)—Henry A. Reisman, M.D.; delegates, W. Guernsey Frey, Jr., M.D., and H. P. Mencken, M.D.; alternates, Morris Bender, M.D., Frank Cerniglia, M.D., and Arthur A. Fischl, M.D.

Schenectady County

Dr. William F. Nealon was elected president of the county medical society at the annual meeting on December 3 at the Mohawk Golf Club. He succeeds Dr. Joseph H. Cornell.

Dr. Charles F. Rourke was elected vice-presi-

dent, the position formerly held by Dr. Nealon, and Dr. Nelson H. Ruse was elected secretary to replace Dr. Gomer Richards. Dr. Alfred S. Grussner, who assumed the office of treasurer when Dr. Raymond H. Warner was called into active service, was named to that office.

Dr. Cornell, Dr. Harry E. Reynolds, and Dr. William L. Fodder were elected to the board of censors. Dr. F. Leslie Sullivan was elected delegate to the state organization with Dr. Rourke as alternate and Dr. Beverly L. Vosburgh was elected delegate to the fourth District branch with Dr. Ralph D. Reid as alternate. Dr. E. MacDonald Stanton was elected to the compensation committee.

The meeting followed a dinner. Entertainment followed the meeting.*

"A portable emergency medical field set for use by physicians in case of bombings, sabotage, or other emergencies was presented to Dr. James M. Blake, chief of the emergency medical service of Schenectady County on December 7 at the Schenectady County Tuberculosis Hospital, Glenridge Road, by Dr. Joseph Peter Huguot, national medical director of the Medical and Surgical Relief Committee of America. This is the second set presented by the committee to Schenectady defense officials and the fifty-third to various officials in New York State.

"The presentation marked the official opening of a week's drive throughout the county for the collection of surplus medical and surgical supplies and for funds to purchase additional sets for the U.S. coast guard and emergency stations in target areas throughout the United States and Alaska.

"The name of any individual or group who contributes the cost of a set (\$110) will be inscribed on a name plate affixed to the set.

"The drive was conducted under the joint auspices of the Emergency Medical Service of Schenectady County Medical Society under the direction of Dr. Blake, Mrs. Charles F. Rourke, and Mrs. William M. Mallia.*

Schoharie County

Dr. Ward L. Oliver, prominent Cobleskill physician, has been appointed district medical officer of the Health Preparedness Commission of the New York State War Council, it was recently announced in a local newspaper.

He will be stationed in Albany and will direct the emergency services in twenty-five counties of the northern district of the office of civilian protection. He reported for duty December 1.*

Tioga County

The annual meeting of the county medical society was held in November following a dinner meeting at the Green Lantern Inn, Owego, New York.

The minutes of the October meeting were read and approved.

The panel for officers for 1943 was read. There were no additional nominations. Dr. Moulton moved and Dr. Johnson seconded that one ballot be cast for the panel nominated, carried and the following officers declared elected for 1943: president, J. B. Schamel, M.D.; vice president, H. L. Knapp, Jr., M.D.; secretary

cent in excess of the rated capacity of the hospitals, and is at present about 15 per cent.

Additional subjects that still need study were listed as follows:

The system of records and reports in regard to patients; admissions; the bearing of syphilis control measures on the future population of State hospitals; research as to possible relationships of inadequate nutrition to mental illness; and vocational training, adjustment, and employment of patients after parole or discharge.

Mr. Folks emphasized that successful operation of parole and family care requires care in the selection, supervision, and follow-up of patients returned to the community.

Members of the Commission

The Commission appointed by the Governor consisted of Homer Folks, secretary of the State Charities Aid Association, as chairman; Stanley P. Davies, Ph.D., executive director of the Community Service Society of New York, whom the Commission appointed as its vice-chairman; Dr. Clarence O. Cheney, medical director of the Westchester Division of the New York Hospital; Miss Hester B. Crutcher, director of Psychiatric Social Work, State Department of Mental Hygiene; Dr. Lawrence Kolb, of the U.S. Public Health Service; Dr. Nolan D. C. Lewis, director, New York State Psychiatric Institute and Hospital; Dr. Frederick W. Parsons, former commissioner of Mental Hygiene; Dr. William L. Russell, consulting psychiatrist, Payne Whitney Psychiatric Clinic, New York; Dr. George S. Stevenson, medical director, National Committee for Mental Hygiene; Dr. William J. Tiffany, commissioner of mental hygiene, and Dr. Karl Bowman, of Bellevue Hospital, who removed to California in November, 1941.

Miss Katharine G. Ecob, executive secretary of the State Committee on Mental Hygiene of

the State Charities Aid Association, served as secretary of the Commission, and Miss Edith Holloway, formerly assistant director of the Family Welfare Association of the District of Columbia, as assistant secretary.

The Commission created a Committee on Newer Modes of Treatment, headed by Dr. Nolan D. C. Lewis as chairman, and a Committee on Parole and Family Care, with Stanley P. Davies as chairman.

Dr. Frank F. Tallman, director of clinical psychiatry at the Rockland State Hospital, was detailed to the Commission as director of its Committee on Parole and Family Care, and served until he accepted a position in Michigan. He was succeeded on the Commission's staff by Dr. Neil D. Black, of the Marcy State Hospital.

Miss Holloway made for the Commission "A Study of Social Services to Paroled Patients from Rockland State Hospital," and Miss Sue H. Mason, of the staff of the Brooklyn Bureau of Charities, "A Study of Social Service to State Hospital Patients Paroled in New York City." The Commission's report stated that the purpose of these two special studies was to throw light on the value of adequate social service in handling paroled patients and to better organization of parole in New York City. They included extremely interesting outlines of case histories in which the friendly and sustained interest of social workers was a dynamic factor in the rehabilitation of patients.

Dr. Benjamin Malzberg, of the Statistical Bureau of the State Department of Mental Hygiene, was loaned to the Commission to study extensive (but as yet incomplete) data on the results of insulin and other shock treatments in the State hospitals, and a detailed memorandum from him on the subject was included as an "Appended Paper" with the Commission's report.

Improvements

The bed capacity at Nathan Littauer Hospital in Gloversville will be increased about thirty in order to meet the steadily increasing demand for local hospital facilities, it was announced at a meeting of the board of directors, held in November. This would boost the beds from 150 to 180.

Increasing the present capacity of the hospital can be accomplished, hospital authorities said, by utilizing now unused space. Thus, it will not be necessary actually to enlarge the building.

It was stated that the minor changes necessary to make available this additional space would cost only a few hundred dollars. Immediate steps are being taken to accomplish this enlargement.

This is the second time in about two years that it has been necessary to expand the bed capacity at the hospital.*

Sidney Hospital construction is progressing rapidly and it is hoped that on or about February 1 it will be ready for use. This has been made possible by government funds of \$133,000, a bond issue in the town of Sidney of \$35,000, and

by funds raised by a campaign conducted in the Scintilla plant by the Employees Ignition Association, and a house-to-house canvass made by the women of Sidney and Sidney Center. However, it is necessary to raise a little over \$5,000 in order to assure the opening by February 1.

In addition to these, a substantial donation of \$10,000 has been made by the Scintilla plant, \$2,000 by the Unadilla Silo Company of Unadilla, and several smaller donations of \$300 or more by interested people in and around Sidney.*

The Veterans' Memorial Hospital in Ellenville has recently received from the Davella Mills Foundation a contribution for the purchase of new and additional equipment in the sum of \$1,000. This contribution was received through the efforts of Miss Elizabeth Keeler, a former resident of this village and daughter of Mrs. Addie Ernoudt.*

The Arnot-Ogden Hospital in Elmira, has opened an unused section, with beds for 21

* Asterisk indicates that item is from local newspaper.

Hospital News

Louis H. Pink Named President of Three-Cents-A-Day Hospital Plan

ASSOCIATED Hospital Service of New York has announced the election of Louis H. Pink, New York State Superintendent of Insurance since 1935, as president of the non-profit three-cents-a-day plan which protects 1,300,000 New Yorkers against unforeseen hospital bills.

Mr. Pink will fill the vacancy created on October 22 by the death of Dr. S. S. Goldwater.

Long experienced in social, educational, and charitable activities, Mr. Pink will assume his new duties at the moment Associated Hospital Service of New York is devoting its effort toward large-scale cooperation with Community Medical Care, Inc., which extends similar low-cost protection to subscribers of Associated Hospital Service against surgical expense up to \$150 at a cost of a few cents a day.

Mr. Pink has been connected with the State Insurance Department for ten years. He has been Superintendent of Insurance for seven and a half years, which is the longest term one man has filled that office since the first superintendent, William Barnes, served for ten years, beginning in 1859.

Recently Mr. Pink has been serving as co-ordinator between state insurance commissioners and the Federal government in trying to bridge the gap between government and private war damage insurance.

He is chairman of the board of the National Public Housing Conference, member of the executive committee of the National Association of Insurance Commissioners, and vice-chairman of the board of trustees of St. Lawrence University.

Mr. Pink will be assisted by the present officers of the Associated Hospital Service of New York.

They include David H. McAlpin Pyle, chairman of the executive committee; Frank Van Dyk, vice-president in charge of enrollment and subscriber relations; Dr. Paul Keller, vice-president and medical director; Paul G. Drescher, vice-president and comptroller; Harry Sesan, vice-president and auditor; Allen B. Thompson, vice-president and actuary; and James de Socarras, secretary. He has been treasurer of the New York Child Labor Committee for many years. He was appointed to the State Housing Board in 1927 by Governor Alfred E. Smith and later became chairman of the board. It was his work with the Housing Board that made him first choice for the State Insurance position.

He takes over the leadership of Associated Hospital Service of New York at a time when living costs, income taxes, and other expenses make protection against the cost of hospital and surgical care doubly important to the average American. Seventy-six hospital service organizations using the Blue Cross Plan have been created throughout the country and are now affording protection to 10,000,000 Americans. Associated Hospital Service of New York is the largest of these nonprofit groups.

On October 31, 1942, the New York Plan, although not yet eight years old, had assets of \$9,894,082.99. In addition to a voluntary \$2,000,000 reserve for epidemics and other possible emergencies, it had a surplus of \$5,121,865.19 for protection of its subscribers.

Since its formation in 1935, the organization has paid more than \$37,000,000 to the hospitals that care for its subscribers, of whom approximately 400 are admitted daily to hospitals. Last year's payments alone amounted to almost \$7,000,000.

Decrease in Insane Patients in State Hospitals

FOR the first time in fifty years since New York State assumed care of the insane, the rate of increase in the number of patients in residence in civil State hospitals has not only been halted, but the number is decreasing. Governor Lehman was recently informed by the Temporary Commission on State Hospital Problems, which he named on November 9, 1940, to survey the continually growing population of these nineteen institutions.

Members of the Commission, headed by Homer Folks, its chairman, have submitted a progress report on the survey of the Commission and the successful steps which it recommended, initiated, and helped the State Department of Mental Hygiene and the State hospitals to put into effect to check the yearly increase in the number of insane requiring institutional care.

The Commission not only reported that it is possible to reduce the number, but that this actually has been accomplished.

A high light of the report was that during the

four months ending November 1 this year, the number of patients in residence in hospitals had for the first time decreased. The Commission believes that if the psychiatric and social service personnel of the hospitals is not too seriously depleted by war, the number may be kept down, and even further decreased.

The report stressed as the chief factors in the notable decrease the increase in and the earlier use of parole, the boarding out of larger numbers of carefully selected patients in family homes, and progress in testing and using new methods of shock treatment. The survey was made with the full cooperation of the State Department of Mental Hygiene and the hospitals.

In appointing the Commission, the Governor stated that the annual increase had averaged 2,392 patients a year for the last ten years. To provide beds for the steadily increasing patient population, the State has spent large sums both from current appropriations and bond issues, but without ever being able to eliminate overcrowding which, at times, has been as high as 35 per

The White Plains Hospital Association presented the second of its current series of six public health lectures on Monday evening, November 9. The speaker was Dr. Iago Galdston, Director of the Medical Information Bureau of The New York Academy of Medicine. His subject was the "Story of Modern Medicine." It was most enthusiastically received. The second lecture in the series was on December 14, at 8:30 p.m., and the speaker was Dr. Alan Gregg, Director for the Sciences of the Rockefeller Foundation. He spoke on "Modern Medicine in China."

These lectures are jointly sponsored by the hospital, the County Health Department, and the County Medical Society.

. . .

Contrary to the announcement carried in last month's *Bulletin*, we now learn that the Yonkers Professional Hospital is still accepting patients. Negotiations on the rental of its premises have been reopened and it is hoped that a settlement can be reached which will permit this institution to carry on indefinitely.—*Westchester Med. Bull.*

. . .

The modern, only partially completed group of buildings New York State is constructing for the Willowbrook School for Mental Defectives at Willowbrook, Staten Island, will be operated by the Army Medical Corps as a wartime hospital, Col. Frank G. Devoe has announced.

Colonel Devoe and a staff of 100 already have moved into the hospital and are preparing it for use. Actual operation will not begin, however, until negotiations with the city and the state are completed, he said.*

. . .

Dr. Walter Rathburn, superintendent of Newton Memorial Hospital, told the story of Chautauqua County's fight against tuberculosis in a talk before the annual meeting of the medical society of that county. This fight, he said, began in 1913, when \$150,000 was bequeathed by Mrs. Elizabeth Newton, a lifetime resident of Fredonia, to erect a county tuberculosis institution. The Newton Memorial Hospital was erected in memory of Mrs. Newton's two sons. The scope of this work has increased in the succeeding years, with the opening of additional clinics and the addition of new buildings.

. . .

Dr. David W. Park, of New York City, inspector of Welfare Institutions in New York State for over forty years, recently assumed his duties as superintendent of Potsdam Hospital, replacing Arthur R. Carvolth, who has entered military service, after being in charge of the hospital since December 29, 1940.*

. . .

Dr. William Ryan has been named by the board of managers of the Montgomery Sanatorium to succeed Dr. William A. Bing, who has retired.

Dr. Ryan, formerly a resident of Syracuse, is a graduate of Syracuse University Medical School and was at one time connected with the Schenectady County tubercular hospital. He comes from the Herman Biggs Memorial Hospital at Ithaca, where he was stationed for about four years.

Dr. Stella Partyka, who has been temporarily in charge of the sanatorium since the resignation of Dr. Bing, during the early summer, will remain as assistant medical director.*

. . .

Courses in the Kenny System of treating infantile paralysis will be given for registered nurses of Westchester after January 1 at Grasslands Hospital, Dr. William A. Holla, County Health Commissioner, announced at a demonstration of the method held in November before about 250 county physicians, medical students, and nurses in New York Hospital, Westchester Division.

The training center will be under the direction of the County Health Department, Grasslands Hospital, and the Westchester Chapter of the National Foundation for Infantile Paralysis.*

. . .

Scientists employed their unique method of honoring a distinguished confrere in paying tribute to Dr. Bernard Sachs, noted neurologist, for "sixty years' participation in the progress of medicine" at a ceremony at the Mount Sinai Hospital on November 24. A volume of original papers on scientific research specially contributed for this purpose by noted physicians and scientists in America and abroad was presented to Dr. Sachs on this occasion.

From a surgeon in the British Navy aboard a battleship somewhere at sea, from a scientist in occupied Denmark, and from 81 other physicians and research workers, these papers were contributed for the 700-page presentation volume, a special issue of the *Journal of the Mount Sinai Hospital*. The presentation was one of the notable events in connection with the observance by Mount Sinai Hospital of its ninetieth anniversary.

The volume is a gift from 102 physicians, friends, associates, and former students of Dr. Sachs.

. . .

Dr. Sidney W. Bisgrove, first assistant physician at the Marcy State Hospital since 1931, became superintendent of the Syracuse State School on November 1.

A veteran of twenty-one years' service with the Utica State and Marcy Hospitals, he succeeds Dr. Charles E. Rowe, who died July 30, 1942.*

Physical ills are the taxes laid upon this wretched life; some are taxed higher, and some

lower, but all pay something.—*Lord Chesterfield, Letter to his son*

patients, including eleven private rooms and two semiprivate rooms of five beds each.

St. Joseph's Hospital has reopened the sixth floor with accommodations for 26 patients.

The Arnot-Ogden floor is furnished with new equipment for which Superintendent William D. Entley began negotiating last May.*

. . .

The Hubbard Tank, device for the treatment of infantile paralysis, is now in use at Albany Hospital for all chronic polio patients in the county.

Also available to other crippled children, the tank was dedicated on November 19 by members of the Albany Chapter of the National Foundation for Infantile Paralysis and the Albany

Association for the After-Care of Infantile Paralysis, Mayor Corning, and hospital officials.

The stainless steel tank was purchased for the hospital by the county chapter of the National Foundation with part of the funds raised in the campaign last January. Installation and operating costs are being paid by the hospital. The city will pay the salary of a physiotherapist. The After-Care Association has donated its ambulance, with driver and orderly, to carry patients to and from the hospital.*

. . .

According to the *Ulrich Press*, December 7, the new federal hospital there "must be built by April 15."

Newsy Notes

The Department of Hospitals in New York City has put into effect a series of pay increases for employees in the lower-paid categories. Commissioner Edward M. Bernecker has posted announcements revealing his pleasure at being able to do something toward eliminating the important grievance of low salaries.

Here is the new schedule:

Nurses, previously earning \$900 and \$1,260 a year, get an increase of \$150, or an additional \$3 a week in the pay-check.

Hospital helpers, previously earning \$480 with maintenance and \$780 without maintenance, get an additional \$120.

Hospital attendants, earning \$540 with maintenance and \$480 without maintenance get an additional \$120 a year.

Practical nurses—same schedule as hospital attendants.

Laundry workers—same schedule as hospital attendants.

Cooks, previously earning \$960 with maintenance and \$1,200 without maintenance, an additional \$150 a year.

Others getting salary raises of \$120 a year are seamstresses, barbers, and tailors.*

. . .

The new line-up of promotions and war leaves among the top-ranking people in the New York City Department of Hospitals, effective December 1, are as follows:

Dr. Israel Magelaner, medical superintendent of Harlem Hospital, to medical superintendent of Kings County Hospital, for the duration, in place of Dr. Emanuel Giddings, who has become a colonel in the Army.

Dr. Emanuel Lifshutz, deputy medical superintendent at Kings County, to medical superintendent at Harlem Hospital, in place of Dr. Magelaner.

Dr. Alexander Kruger, medical superintendent of Lincoln Hospital, to medical superintendent of Metropolitan Hospital, in place of Dr. I. Herbert Scheffer, who has become a major in the Army.

Dr. Henry W. Kelbe, deputy medical superintendent of Metropolitan Hospital, to medical superintendent of Lincoln Hospital, in place of Dr. Kruger.

Dr. Stephen H. Ackerman, medical superintendent of Fordham Hospital, to medical superintendent of Coney Island Hospital, in place of Dr. R. A. Wyman, who has become a major in the Army's Public Health Service.

Dr. Nathan Smith, deputy medical superintendent of Morrisania Hospital, to medical superintendent of Fordham Hospital, in place of Dr. Ackerman.

Dr. Samuel A. Schuyler to acting medical superintendent of Triboro Hospital, in place of Dr. Alfred Ring, who has become a captain in the Army.

. . .

New York State needs 1,867 more nurses, according to Miss Emily J. Hicks, executive secretary of the New York State Nursing Council for War Services, in an appeal for young women to take nursing courses to aid in the war effort.

New student enrollments show a 10 per cent increase nationally in the summer and fall classes, Miss Hicks said. "This would make us happy," she commented, "were it not for the fact that a 25 per cent increase would be necessary to reach the government-estimated quota of 55,000 new students this year."

Miss Hicks said that the armed forces of the United States are asking for 3,000 nurses for each month, owing to their expansion.

"Inactive nurses are returning to work to help out in the emergency," she said, "and Red Cross aides, volunteers, and other types of auxiliary workers are proving wonderfully helpful in our hospitals. However, it is to the young people we must look for most of the war work with a future that nursing is, and those midterm enrollments are our next hurdle."

Recruitment committees already are hard at work, and their efforts are being reinforced by the Federation of Women's Clubs, which has offered its services to get enrollees. Miss Hicks suggested that those who are qualified to take up nursing should get in touch with the Nursing Council in their home districts, or write to the State headquarters, 152 Washington Avenue, Albany—*New York Times*, December 7.

. . .

NOW!

A Revolutionary Development in Intranasal Sulfonamide Therapy

PAREDRINE-SULFATHIAZOLE SUSPENSION combines, for the first time, in a single stable preparation the effective vasoconstriction of 'Paredrine'* and the potent bacteriostatic action of sulfathiazole.

This preparation owes its remarkable effectiveness largely to the newly-developed 'Microform'* crystals—*approximately 1/1000 the mass of ordinary sulfathiazole crystals*. These crystals—pictured at lower right—form a suspension which: (1) approximates a solution in its ease of application... (2) deposits the sulfathiazole uniformly... (3) passes freely through the ostia of the sinuses.

Therefore, Paredrine-Sulfathiazole Suspension represents a revolutionary development in the treatment of nasal and sinus infections, particularly those secondary to the common cold.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

War Medicine and Surgery

A course in War medicine and surgery has been arranged for the Oneida County Medical Society. The lectures will be given at Hutchings Hall, Utica State Hospital, in Utica, at 8:30 P.M.

January 26—"Nervous Conditions Associated with Warfare"

Foster Kennedy, M.D., professor of clinical medicine (neurology), Cornell University Medical College, New York City.

February 2—"General Principles of Treatment of War Injuries"

Philip Duncan Wilson, M.D., clinical professor of orthopedic surgery, Columbia University, College of Physicians and Surgeons. Address: Hospital for Ruptured and Crippled, 321 East 42nd Street, New York

City. (Dr. Wilson has recently returned from England.)

February 9—"The Care of Soft Tissue Injuries" Forrest Young, M.D., assistant professor of surgery, University of Rochester School of Medicine and Dentistry, Strong Memorial Hospital, Rochester, New York.

February 16—"Epidemiology and Control of Syphilis"

James H. Lade, M.D., assistant director, Division of Syphilis Control, State Department of Health, Albany, New York.

At this meeting the motion picture film (technicolor and sound) entitled "Syphilis," which is provided by the State Department of Health, will be shown.

This instruction is a cooperative endeavor between the Medical Society of the State of New York and the New York State Department of Health.

Treatment of Common Diseases

A series of four lectures on "The Treatment of Common Diseases" were presented before the Madison County Medical Society during November and December. They were arranged by Dr. Clayton W. Greene of the University of Buffalo College of Medicine and took place in the Hotel Oneida, Oneida, at 8:30 P.M. The subjects and speakers were as follows:

November 24—"Evaluation of Common Drugs Used in General Practice," by A. H. Aaron, M.D., professor of clinical medicine, University of Buffalo School of Medicine.

December 1—"What Do We Know About

Vitamins?" by David K. Miller, M.D., professor of medicine, University of Buffalo School of Medicine.

December 8—"The Treatment of Burns," by J. Sutton Regan, M.D., assistant professor of surgery, University of Buffalo School of Medicine.

December 15—"Practical Application of Hormonal Therapy," by Clyde L. Randall, M.D., professor of gynecology, University of Buffalo School of Medicine.

THE NEW YORK ACADEMY OF MEDICINE ELECTS OFFICERS

The New York Academy of Medicine on December 3 elected the following officers:

Arthur F. Chace, M.D., president for a term of two years.

Cornelius P. Rhoads, M.D., vice-president for a term of three years.

Robert E. Pound, M.D., secretary for a term of three years.

Malcolm Goodridge, M.D., and Harold R. Mixsell, M.D., trustees for a term of five years.

Kirby Dwight, M.D., trustee to fill unexpired term of Dr. Chace through 1945.

Edward F. Hartung, M.D., R. Townley Paton, M.D., and Philip Van Ingen, M.D., members of Committee on Library for a term of three years.

Ruth M. Bakwin, M.D., Thomas K. Davis, M.D., Locke L. Mackenzie, M.D., and Thomas G. Tickle, M.D., members of Committee on Admission for a term of three years.

Lewis B. Robinson, M.D., member of Committee on Admission to fill unexpired term of Dr. Scarff through 1943.

Federal Legislation

The following bulletin (No. 22) was issued on December 1, 1942, by the Bureau of Legal Medicine and Legislation of the American Medical Association.

Army Nurse Corps; Dietitians and Physical Therapy Aides in Army Medical Department

H.R. 7633 has passed the House of Representatives, increasing the pay and allowances of members of the Army Nurse Corps and providing for the inclusion in the Medical Department of the Army of such female dietetic and physical therapy personnel as the Secretary of War may consider necessary.

The bill provides that during the present war and for six months thereafter (1) the members of the Army Nurse Corps shall have relative rank and receive pay and allowances, including mileage and other travel allowances, as now or hereafter provided by law, for commissioned officers, without dependents, of the Regular Army in the sixth to the first pay periods, respectively; (2) there shall be included in the Medical Department of the Army such female dietetic and physical therapy personnel (exclusive of students and apprentices) as the Secretary of War may consider necessary, whose qualifications, duties, and assignments shall be in accordance with regulations to be prescribed by the Secretary, and who shall be appointed and, at his discretion be removed, by the Surgeon General, subject to the approval of the Secretary, such personnel having relative rank and receiving pay and allowances, including mileage and other travel allowances, as now or hereafter provided by law, for commissioned officers, without dependents, of the Regular Army in the third to the first pay periods, respectively.

The superintendent of the Army Nurse Corps will receive pay and allowances of the sixth pay period (\$333.33-\$400 base pay) and will have the relative rank of colonel; assistant superintendents or directors will receive pay and allowances of the fifth or fourth pay periods (\$250-\$350 base pay) and will have the relative rank of lieutenant-colonel or major, respectively; one chief dietitian to be designated as the Director of Dietitians and one chief physical therapy aide to be designated as the Director of Physical Therapy Aides will each have the relative rank of major and receive the pay and allowances of the third pay period (\$200-\$240 base pay); assistant superintendents and assistant directors, chief dietitians and chief physical therapy aides will also receive the pay and allowances of the third pay period and will have the relative rank of captain; chief nurses, head dietitians and head physical therapy aides will receive the pay and allowances of the second pay period (\$166.67-\$199.99 base pay) and will have the relative rank of first lieutenant; and head nurses, nurses, dietitians, and physical therapy aides will receive pay and allowances of the first pay period (\$150-\$180 base pay) and will have the relative rank of second lieutenant.

As indicated in its title, this bill generally will increase the base pay and allowances for members of the nurse corps. For instance, under the existing pay schedule a nurse with under three

years of service receives \$90 base pay. Under the pending bill, that nurse will receive \$150. A chief nurse at present with under three years of service receives \$140. Under the pending bill she will receive \$166.67. Similar increases are provided for in the other classifications except, apparently, in the case of assistant directors of nurses who, according to a schedule published in the Report of the House Committee on Military Affairs, now receive \$215 a month if they have served for only three years as assistant directors, while under the provisions of the pending bill they will receive \$200 a month base pay during that period.

With respect to female dietitians and female physical therapy aides, the Report of the House Committee on Military Affairs points out that they have been employed by the War Department in a strictly civilian capacity for many years with no authority or status in the Army. At the present time 591 dietitians are so employed and 386 physical therapy aides. It is estimated that by June 30, 1943, the services of 1,448 dietitians will be required and 1,386 physical therapy aides. Dietitians employed by the Medical Department are required, states the report, to be graduates of a recognized school, and to have majored in dietetics and nutrition, or to have received a bachelor's degree from a recognized college with a major in dietetics, food preparation, nutrition, and institutional management. Physical therapy aides are required to be graduates of a recognized school of physical therapy or to have completed a four-year course in physical education.

The Committee Report points out that with the establishment of Army hospitals in combat zones, and the assignment of dietitians and physical therapy aides to them, it will be essential that they be given military status. "In other times a theater-of-operations hospital," the Committee states, "was comparatively safe from attack or capture, but in the present war these civilians are more liable to become injured or to be taken prisoner and they should therefore have the same protection, pay and allowances, insurance, pension, and other gratuities as our nurses alongside whom they work in Army hospitals. It is not contemplated that women of other categories will be sent overseas for duty in Army hospitals."

Rear Admiral in Dental Corps of Navy

S. 2769 has been reported to the Senate, authorizing the rank of rear admiral in the Dental Corps of the United States Navy. According to the Report of the Senate Committee on Naval Affairs, this bill was sponsored by the American Dental Association. A representative of that Association appeared before the Committee in support of the bill, stating that the Army Dental Corps is allowed one brigadier general as assistant to the Surgeon General of the Army, that in

NEW YORK, N. Y.

WINDSOR, ON

[Continued from page 78]

the opinion of the Association the Army Medical Corps has benefited by having one officer of this rank and that it was rather humiliating to officers of the Dental Corps of the Navy to feel that they are entitled to reach only the rank of captain after many years of service, while officers of other staff corps are able to attain the rank of rear admiral.

The Navy Department made an adverse report on the bill, stating in part as follows:

"The Dental Corps of the Navy is a division of the Medical Department and the affairs of the Dental Corps are under the general direction of the Chief of the Bureau of Medicine and Surgery. In other bureaus of the Department there are similar divisions corresponding to that of the Dental Corps. There is no provision whereby these divisions should be headed by an officer of the rank of rear admiral.

"The Navy Department considers that the establishment of the rank of rear admiral in the Dental Corps of the Navy as contemplated by the proposed legislation would serve no useful purpose, and therefore accordingly recommends against its enactment."

The Committee Report points out that the present authorized strength of the Dental Corps of the Regular Navy is 527. As of September 1, 1942, there were 412 regular officers, 1,109 Naval Reserve officers, and 7 retired officers of the Dental Corps on active duty, making a total on that date of 1,528 officers of the Dental Corps. The pending bill, the Committee reports, does not change the relation of the Dental Corps to the Medical Department of the Navy; it merely gives dental officers an opportunity for promotion to the rank of rear admiral. The Committee felt that the passage of this bill would constitute a recognition of the important contribution made by dental officers of the Navy.

Protection of Blind Persons under Civil Service

S. 2902, introduced by Senator Davis of Pennsylvania, November 20, and pending in the Senate Committee on Civil Service. A bill to prevent discrimination against blind persons and persons with impaired visual acuity in the administration of the civil service laws and rules.

Comment.—This bill proposes to amend the act to regulate and improve the civil service of the United States by providing that no person shall be discriminated against in any case because of

his or her blindness or impaired visual acuity, in examination, appointment, reappointment, reinstatement, reemployment, promotion, transfer, retransfer, demotion, removal, or retirement.

Osteopaths as Commissioned Medical Officers in the Navy

H.R. 7672 has been signed by the President, making supplemental appropriations for the national defense for the fiscal year ending June 30, 1943, and for other purposes (Public Law No. 763). At the time this bill was before the Senate for consideration an amendment was submitted by Senator Downey, of California, providing that the appropriations for the Navy Department shall be available "for the pay of commissioned officers who are graduates of reputable schools of osteopathy." The following discussion on the amendment ensued:

"MR. DOWNEY: Mr. President, I wish to offer an amendment to the pending bill which I have discussed with the Senator who is sponsoring the measure (Senator McKellar of Tennessee). The amendment is on page 8, line 17, after the word 'law,' to add the words 'for the pay of commissioned medical officers who are graduates of reputable schools of osteopathy.'

"I may say, in relation to the amendment, that there is at the present time no provision in the law by which payment can be made by the Navy to commissioned medical officers who are graduates of schools of osteopathy. The Navy is of the opinion, I understand, that some time during this year it may desire to commission officers who are graduates of schools of osteopathy. The provision is merely permissive, and in case the Navy should desire to make such appointments, this amendment would permit that to be done.

"Mr. President, I understand the distinguished Senator from Tennessee (Mr. McKellar) is willing to take the amendment to conference.

"MR. MCKELLAR: Yes. I have no objection to doing so.

"THE VICE-PRESIDENT: The question is on agreeing to the amendment of the Senator from California (Mr. Downey).

"The amendment was agreed to."

The conferees permitted the amendment to remain in the bill.

J. W. HOLLOWAY, JR., *Director*

UROLOGY AWARD

The American Urological Association offers an annual award "not to exceed \$500" for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented, and if the Committee on Scientific Research deem none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in

such specific practice for not more than five years.

The selected essay (or essays) will appear on the program of the forthcoming meeting of the American Urological Association, May 31–June 3, 1943, Hotel Jefferson, St. Louis, Missouri.

Essays must be in the hands of the Secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tennessee, on or before March 1, 1943.

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

Woman's Auxiliary

To the Medical Society of the State of New York

THE year 1942 has drawn to a close and we hail the New Year 1943.

May brightly shining candles
Light your heart with cheer,
And symbolize the gladness
That's wished you through the year.

Our president-elect sends New Year's greetings to all:

We as members of the Woman's Auxiliary to the Medical Society of the State of New York are beneficiaries of a way of life that offers wider opportunities than are found in any other association of women. We have a corresponding obligation to use our energies with the utmost intelligence and devotion to preserve that way of life when it is threatened. This is our "Challenge for the New Year."

Remember that our duty is of huge dimensions. Because of the present tumultuous struggle, our doctors have been called upon to perform a gigantic task—to preserve the health of the

civilian population. And our third obligation is to uphold the ethical and educational standards of the medical profession.

We, the wives of doctors, cannot relieve the sufferings of the armed forces, but we can remember the wives of the men who have left to care for our fighting men. These women need our support. Do not forsake them.

We can assist in keeping the health of the civilians at the high level it was before this conflict began by giving watchful attention to the health and happiness of others. We can teach the public the benefits of proper nutrition and preventive medicine by giving health forums and nutrition exhibits, with lectures on nutrition.

We must sustain the prestige of the medical profession by keeping ourselves informed and educated. Read medical literature, study medical legislation, and be alert to all medical problems. We shall not fail.

This is my sincere plea to all my fellow members for this year of 1943.

MRS. F. LESLIE SULLIVAN, *President-Elect*

County News

Albany. The November auxiliary meeting was held in the Canary Room, DeWitt Clinton Hotel, in Albany. Mrs. John B. Horner presided and Mrs. Thomas Fitzgerald gave a talk on the work of the War Council. A membership tea was held, at which six new members were welcomed. Fifty old members and ten guests were present. The annual card party, which is held each fall, and which was under the chairmanship of Mrs. Emerson C. Kelly and her committee, proved very successful—\$200 was raised. A portion of this sum was donated to the Hospital for Incurables, in Albany, for two special-type beds needed there.

Each member of the auxiliary contributes something to the selling of War Stamps and Bonds.

Nassau. Dr. Earle G. Brown and Dr. Roland T. Jeffrey were guest speakers at the auxiliary meeting. They discussed "National Defense," stressing what we, as doctors' wives, can do to best help our country in this great crisis. Mrs. Arthur D. Jacques, president, presided at the meeting. Mrs. Vincent Webb and Mrs. Ray M. Bowles acted as hostesses for the social hour.

Queens. Mrs. William Godfrey presided at the annual meeting held at the Medical Society Building in Forest Hills. Mrs. James Robbins was elected president and Mrs. Harry Meucker, president-elect. The new officers were installed at a luncheon held in December. Mrs. Thomas D'Angelo, defense chairman, sent holiday greetings to all members of the Medical Society of the County of Queens who are in the service.

Saratoga. Mrs. James F. Roohan was re-elected president of the Saratoga County Medical Society's auxiliary at the annual meeting. Much patriotic work was reported. Dr. William H. Ordway thanked the group for serving coffee and sandwiches to blood donors. Mrs. Fred J. Pratt,

Mrs. Arthur J. Leonard, and Mrs. Malcolm J. Magovern were the committee for such recent service. Machine-sewing is to be started for the hospital, and Mrs. H. Dunham Hunt has taken over the work and has asked for more blankets, either old or new, to be used in the air raid shelters. The names of the owners are to be attached to the blankets so that they can be returned later on. A gift of \$4.24 was received from the school children of Mechanicville, Grade 8A3, for the air raid shelter equipment. The auxiliary is outfitting these shelters.

A Christmas party was held at the Nurses Lounge in Cramer House.

Suffolk. The second district branch meeting was held in Garden City, with Suffolk County auxiliary as the hostess. Mrs. J. Emerson Noll State president, was guest of honor. A delightful luncheon was served. Members from Kings, Queens, and Nassau were present. Dr. Cottis, president of the State Medical Society, spoke at the luncheon. Dr. Joseph Lawrence spoke on "Legislation." The general chairman was Mrs. George P. Bergmann, president of Suffolk County auxiliary. A needle-point footstool was given to the auxiliary, on which \$100 was realized. This sum is to be used for charity.

Schenectady. The November meeting of the auxiliary was held at the Hotel Van Curler, with Mr. H. A. Rosen, of the Medical and Surgical Relief Committee of America, as guest speaker. Donations were received to fill Christmas stockings that were distributed to the ward patients in the Ellis Hospital on Christmas Day. Rapid progress is being made in the knitting of two afghans by the committee members. These, when finished, are to be presented to the Red Cross. A membership tea was held in December, at the home of Mrs. William Gazeley.

Fundamentals of Psychiatry. By Edward A. Strecker, M.D. Duodecimo of 201 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1942. Cloth, \$3.00.

IPRAL

BY PROVIDING a sound, restful sleep closely resembling the normal Ipral helps the patient rebuild vital resources. Dosage is small . . . absorption and elimination rapid . . . and cumulative effects avoidable by proper dosage regulation. Ipral has been used for more than 15 years as a safe, effective sedative.

HOW SUPPLIED:

IPRAL CALCIUM (*calcium ethylisopropylbarbiturate*) in 2-grain tablets and in powder form for use as a sedative and hypnotic. $\frac{3}{4}$ -grain tablets for mild sedative effect throughout the day.

IPRAL SODIUM (*sodium ethylisopropylbarbiturate*) in 4-grain tablets for pre-anesthetic medication.

Spencer Abdominal Supporting Corset shown open revealing inner support. This is a SEPA-RATE section, adjustable to the corset section and the patient's figure by means of flat tapes that emerge on outside of corset.

When you prescribe a Spencer Support y are assured it will meet your specific requirments and the patient's figure needs, *becau* it will be individually designed, cut and ma for the one patient who is to wear it.

Every Spencer Support is individually designed for patient of non-elastic material. Hence, the support provides is constant, and a Spencer can be—and it guaranteed NEVER to lose its shape. Spencer Suppo have never been made to *stretch to fit*; they have alwa been *designed to fit*. Why prescribe a support that se loses its shape and becomes useless before worn or Spencers are light, flexible, durable, easily laundered

For service, look in telephone book under "Spenc Corsetiere" or write direct to us.

BRUNSWICK HOME

A PRIVATE SANITARIUM. Convalescents, postoperative, aged and infirm, and those with other chronic and nervous disorders. Separate accommodations for men and women. ~~Separate accommodations for men and women.~~ Rigidly followed. C. L. MARKHAM, M.D., Supt.
 B'way & Loudon Ave., Amityville, N. Y., Tel: 1700, 1, 2

DR. BARNES SANITARIUM STAMFORD, CONN.

45 minutes from N. Y. C via Merritt Parkway

For treatment of Nervous and Mental Disorders, Alcoholism and Convalescents. Carefully supervised Occupational Therapy. Facilities for Shock Therapy. Accessible location in tranquil, beautiful hill country. Separate buildings.

F. H. BARNES, M.D., Med. Supt. *Tel. 4-1143

"JOY RIDING" IS OUT

"Joy riding" on railroad trains is now as definitely taboo and unpatriotic as pointless driving of automobiles on the streets and highways. It is difficult for most of us to conceive that anyone ever traveled on the railroads for a "joy ride," not at least since a railroad train was a novelty. Yet, we are being admonished against non-essential travel on the railroads of our country.

What constitutes nonessential travel? No one seems to have defined it satisfactorily as yet. The only answer appears to be "don't—unless you have to." And that raises the point—who does? No one takes a train unless it is the best and only mode of transportation.

But the problems of the railroads are mounting. John J. Pelley, president of the Association of American Railroads, recently gave a statement of the position of the railroads which may give some idea why reservations for railway travel are now so difficult to arrange.

There are approximately 6,800 Pullman sleeping cars and 17,500 passenger day coaches in service on American railroads, and for the duration of this war that's about all there will be.

About 40 per cent of the sleeping cars and 15 per cent of the passenger day coaches are continuously engaged in moving troops, and the armed forces have first call on all the rest.

Besides the special-train and special-car movement of soldiers, sailors, and marines, great numbers of individual service men are traveling either under orders or on furlough and are using regular scheduled trains and cars. On top of that, because of the rubber and gasoline

restrictions, the railroads have been called upon to absorb a considerable percentage of the traffic which formerly moved by highway.

It all adds up to a tremendous increase in railroad passengers—almost double what it was two years ago. Handling the additional load at a time when other war requirements have made it impossible for the railroad to get additional equipment to help carry the added load means that trains are overloaded especially on week end and at holiday times, and train schedules are disrupted. Railroad stations are overtaxed and decent service is impossible on some days and at certain hours.

Much of the civilian travel is on business directly or indirectly connected to the prosecution of the war. Much of it is about imperative personal affairs. Much of it is part of the proper recreation and relaxation which the people of the nation must have if the war effort is to progress as it should. But much of it, also, is unnecessary, and if need be can be dispensed with without undue hardship.

Each traveler knows what his own mission is and should be able to exercise his own discretion as to the necessity or importance of the trip. Certainly the railroad cannot determine who is and who is not entitled to use its facilities, and in a free country has not the right to bar anyone who is willing to pay for the service rendered.

Which still leaves unanswered, "who wants to ride on a train for fun—or to kill time?"

STONY LODGE

COLOR AND EMOTIONS

Under "Recent Items" in the December issue of *Main Currents in Modern Thought*, the following abstract on color and emotions deserves attention.

"The many curious associations and impressions gained by people when the major hues of the spectrum are presented to view were a subject of study made recently by the Color Research Laboratory of the Eagle Printing Ink Corporation.

"Red, as a color, seems hot, dry and opaque in quality, this study showed. Being sharply focused by the eye it suggests angular forms. Orange is less earthly than red. It is warm rather than hot, but it is also dry. Its appearance is glowing and somewhat metallic.

"Yellow is also warm and dry, and also very luminous. Where red is bulky and heavy, yellow is more sunny and spatial. Being the color of highest visibility in the spectrum, it is sharp and precise in form. Green is cool and moist in quality. Blue is cold, wet and suggestive of things transparent—sky and water. Because

FALKIRK IN THE RAMAPOS

A sanitarium devoted exclusively to the treatment of MENTAL diseases. It has been recommended by the members of the medical profession for half a century.

WEST HILL

West 252nd St. and Fieldston Road
Riverdale-on-Hudson, New York City

For nervous, mental, drug and alcoholic patients. The sanitarium is beautifully located in a private park of ten acres. Attractive cottages, scientifically air-conditioned. Modern facilities for shock treatment. Occupational therapy and recreational activities. Doctors may direct the treatment. Rates and illustrated booklet gladly sent on request.

HENRY W. LLOYD, M.D., Physician in Charge
Telephone: Kingsbridge 9-8440

blue is a retiring color and tends to blur on the retina, it suggests round and soft rather than angular forms.

"Purple is cool, refined and extremely atmospheric. It is remindful of shadow and distance. While these generalizations are frankly emotional, they seem to find confirmation in the associations of most people.

GLENMARY SANITARIUM

For individual care and treatment of selected number of Nervous and Mental cases, Epileptics, and Drug or Alcoholic addicts. Strict privacy and close cooperation with patient's physician at all times. Successful for over 50 years.

ARTHUR J. CAPRON, Physician-in-Charge

OWEGO, TIoga CO., N. Y.

PUBLIC HEALTH IN CHINA

The East and West Association's booklet on *The People of China* reveals some interesting points on public health progress in that formerly backward country.

"The death rate in China," states the publication, "has always been very high, chiefly because of cholera and other epidemics, famines and floods. While there is as yet no complete national public health system, and no governmental regulation of food and water, some progress has been made in this direction. The masses are being schooled to have faith in doctors rather than in super-

stitious remedies and quackeries. Also, a number of highly important rural experimental stations have been established.

"Despite the lack of adequate centralized public health facilities, the Chinese have long understood the value of certain herbs and treatments. Ephedrine, ginseng and medicinal rhubarb come to us from China. Chaulmoogra oil obtained from a tree found all over Eastern Asia was used as early as the fourteenth century in China in the treatment of leprosy. Also, while we until recently have looked down on liver, the Chinese have for centuries regarded it as an important tonic. In addition the Chinese have had a very sensible diet, using a great number of green vegetables and the soya bean which we are now discovering to be Nature's miracle food, stuffed with vitamins and minerals. Their uses of hot foods and boiled water in tea have acted as health measures to prevent cholera and other epidemics."

A single lecture has been arranged for a joint meeting of the Onondaga County Medical Society and the Syracuse Academy of Medicine to be held Tuesday Evening, January 5, 1943, 8:30 P.M. in the University Club, Syracuse. The subject is "The Early Treatment of Poliomyelitis with a Description and Evaluation

of the Kenny Technics." The speaker will be Philip M. Stimson, M.D., associate professor of clinical pediatrics, Cornell University Medical College. This lecture is a cooperative endeavor between the Medical Society of the State of New York and the New York State Department of Health.

ortho-gynol

VAGINAL JELLY

A Product of Research

Ortho-Gynol is formulated to meet the most rigid requirements for a vaginal jelly. It is a product of research and has been tested in many authoritative laboratories and in clinical projects in universities and hospitals.

Clinical tests for effectiveness have been supplemented by carefully controlled individual *in vivo* studies. Its use has been favorably commented upon in scientific journals by impartial and authoritative investigators.

its importance in
adjustments of

CIGARETTE SMOKING

WHEN modifications in smoking are in order,* physicians know that the patient's cooperation is extremely desirable. Yet few smokers take kindly to changes in tobacco usage.

Slow-burning Camels can be helpful in this situation. Millions of smokers naturally prefer Camels for their famous mildness and better taste.

Pleased patients mean more reliable records, something to consider if you value cross-section data from group reports.

VITAMINS—high potencies,
low potencies, every dosage form . . .

VITAMINS

Lederle

LEDERLE offers a comprehensive line of single vitamins and vitamin combinations, balanced in accord with the latest findings.

Included are high potency vitamins for *intensive therapy*; high unitage B Complex and Thiamine Hydrochloride for *rapid response* by the parenteral route; lower potency vitamins to serve as *dietary adjuncts*; a variety of dosage forms to suit the preferences of doctor and patient.

As new advances are brought to light, the scientific staff of LEDERLE will keep on revising potencies, adjusting balances, and releasing to the medical profession new vitamin products.

Specify
Lederle

VI-DELTA VITAMINS *Lederle*

- VI-Delta Multi-Vitamins (Capsules), Formula A—A, B Complex, C and D
- VI-Delta Multi-Vitamins (Tablets), Formula B—A, B Complex, C and D
- VI-Delta Emulsion Oral (A and D)
- VI-Delta Capsules (A and D)—for Infants
- VI-Delta Concentrate Capsules (A and D)
- VI-Delta Liquid Concentrate (A and D)

VITAMIN B COMPLEX *Lederle*

- Vitamin B Complex Capsules
- Vitamin B Complex Tablets

Vitamin B Complex Oral
Vitamin B Complex (Parenteral)

SINGLE VITAMINS *Lederle*

- Ascorbic Acid (Vitamin C)
- Calcium Pantothenate
- Menadione (Vitamin K)
- Niacinamide (Nicotinic Acid Amide)
- Riboflavin (B₂ or G)
- Pyridoxine Hydrochloride (B₆)
- Thiamine Hydrochloride (B₁) (Tablets)
- Thiamine Hydrochloride (B₁) (Parenteral)
- Vioosterol in Oil (A.R.P.I.)
- Vitamin A Capsules

The Omnibus of Therapy

In hard-to-define multiple disturbances involving the nerves and nutrition, nothing has been a greater boon to harassed physicians than vitamins of the B complex.

By the action of one or more of its components, vitamin B complex is a vital intermediate in the metabolism of carbohydrates; is necessary to transport oxygen through the epithelium and is essential to respiratory enzyme function; hence is required for the breathing of all cells.

These facts disclose why the complex carries multiple curative effects—why it is the omnibus of therapy. Four convenient dosage forms by Breon provide effective therapy for all patients.

BECAPLETS

Made from yeast fortified with crystalline vitamins, each caplet provides:

Thiamine Hydrochloride (B-1)	1 mg.
Riboflavin (B-2)	1 mg.
Pyridoxine Hydrochloride (B-6)	0.03 mg.
Nicotinamide	6 mg.

In bottles of 100, 500, and 1000

BECAPLETS with Ascorbic Acid
Same as formula above with addition of Ascorbic Acid (Vitamin C).

VITAMIN B COMPLEX SYRUP

From rice bran augmented with crystalline vitamins.

Each 5 cc teaspoonful contains:

Thiamine Hydrochloride	1 mg.
Riboflavin	0.6 mg.
Pyridoxine Hydrochloride	0.5 mg.
Pantothenic Acid	1 mg.
Nicotinic Acid	10 mg.

In 3 oz. and pint bottles

BREONEX-STRONGER

A solution for parenteral injection in 10 cc multiple-dose vials.

Each cc contains:

Thiamine Hydrochloride	10 mg.
Riboflavin	0.1 mg.
Pyridoxine	1 mg.
Nicotinamide	10 mg.

Help for the HARASSED

HEART in HYPERTENSION
MYOCARDITIS and ANGINA PECTORIS

with DIURBITAL

Each DIURBITAL Tablet contains the soluble double salt Theobromine Sodium Salicylate, 3 grs.; Phenobarbital, ½ gr.; Calcium Lactate, 1½ grs. Bottles of 25 and 100 tablets at all pharmacies.

DIURBITAL* helps two ways to relieve the hypertensive heart burdened by vascular disturbance and excessive fluid. DIURBITAL acts to relieve edemic pressure by prompt and efficient diuretic benefits . . . it serves to improve coronary blood flow for better cardiac tone and nutrition.

VASODILATOR, DIURETIC, SEDATIVE and CARDIOTONIC, DIURBITAL affords excellent xanthine effects in gradual and sustained REDUCTION OF ELEVATED BLOOD PRESSURE. Apprehension, dizziness, insomnia and other hypertension syndromes are usually well controlled. . . . No gastric disturbance as DIURBITAL tablets are enteric coated. Prompt and maximum utilization.

WARTIME BOOM IN BABIES

Photograph Camp prenatal support (skeleton indrawn)

Today, more babies are on the way than in any time during the last 20 years! Naturally, there is a corresponding rise in the need and demand for prenatal supports.

The S. H. Camp and Company has developed over a period of more than 30 years—a complete series of maternity supports . . . each type scientifically designed and constructed . . . each type giving accurate support to the abdomen, pelvis, girdle and spinal column.

In fact, not a single detail which will add to their clinical value has been neglected.

That these garments successfully measure up to the most stringent clinical requirements is evident—since they carry the approval of many leading gynecologists and obstetricians throughout the world.

The Camp series of prenatal supports comprise models suitable for all types of build. Patients are asked to return each month for adjustment of their prenatal supports. This service is given free of charge by all Camp-trained fitters.

OWNED AND OPERATED BY THE STATE OF NEW YORK

To ease your load of Chronic Cases

Today, more than ever, the increased number of overworked physicians is entitled to every available facility in the continuing direction and care of chronic cases of circulatory, vascular and rheumatic disorders.

Nature localized at Saratoga a rich endowment of naturally carbonated mineral waters. Here are waters of established therapeutic value in treating conditions where external or internal use of them is indicated. And here New York State has organized and built around these natural agents facilities for your use as a practicing physician.

The Spa (whose medical staff does not practice) administers only the treatments prescribed by you. The local specialist you choose for your patient's stay at the Spa will give the desired supervision. The relaxation achieved at the Spa brings relief from pressures and tensions and thus prepares the patient for the full benefit of your continuing medical direction

We will gladly send you the professional publications of the Spa... physician's sample carton of the bottled waters with their analyses. Address W. S. McClellan, M.D., Medical Director, Saratoga Spa, 155 Saratoga Springs, N. Y.

SARATOGA SPA

THE EMPIRE STATE'S CONTRIBUTION TO THE MEDICAL PROFESSION

A New Peptic Ulcer Therapy with Special Indications

Wyeth's Phosphaljel*, Aluminum Phosphate Gel, is a *special* preparation for use in the treatment of peptic ulcer. Phosphaljel has been found to be effective in gastrojejunal ulcer,¹ which has been called the most resistant type of peptic ulcer.²

Phosphaljel was first employed in an attempt to prevent postoperative jejunal ulcer in Mann-Williamson dogs. With Phosphaljel, ulcers were prevented in twenty of twenty-three Mann-Williamson animals;

furthermore, in a group of animals which developed Mann-Williamson ulcers, the administration of Phosphaljel caused complete healing of the ulcers in nine of ten cases.¹

These striking results led to the successful use of Phosphaljel in the treatment of peptic ulcer in man and disclosed its special usefulness in those cases of peptic ulcer associated with a relative or absolute deficiency of pancreatic juice, diarrhea or a low phosphorus diet.¹

GASTROJEJUNAL ULCER. Most difficult of all to treat satisfactorily—are gastrojejunal ulcers². In these highly resistant lesions Phosphaljel has been found to be effective. Gastrojejunal ulcers may occur after surgical procedures such as that shown below.

SUBTOTAL GASTRECTOMY
(THE HOFMEISTER ANASTOMOSIS)

PHOSPHALJEL

Wyeth's ALUMINUM PHOSPHATE GEL

Dose: One or two tablespoonfuls every two hours, during the active stage of the ulcer. Later in the course of management, three tablespoonfuls with meals and at bedtime, or two tablespoonfuls six times daily with and between meals.

Editorial

War and Social Reform, II*

"Society is an organism subject to all the laws of evolution," said Dr. G. W. Cottis,¹ President of the Medical Society of the State of New York, "and medicine is an organ of vital importance in that organism. There is of necessity a constant interrelationship between the two, and we cannot appraise our situation apart from that of society as a whole." For this reason, we are convinced that at this time editorial emphasis upon social, economic, and political proposals for change is imperative. We have had so much scientific and technical progress in medicine and other fields in so short a time that the great problem now is how to use it in the most efficient and equitable manner. It is by no means a simple problem or one which lends itself readily to scientific analysis, for it involves people, their ideas, their wants, their laws, their industry and agriculture, as well as their ills, and their aspirations.

"Where there is no vision, the people perish," says the Old Testament.² At present, human beings aspire to security, personal and social, economic and otherwise. Well, human beings have always done that, and have, in addition, gone a long way on the road to its attainment.

"Under the smoke and fire of battles we might see all the people of the earth," continues Dr. Cottis, "moving like a tidal wave in one direction. That direction is toward a new form of society

in which independence is replaced by dependence, and freedom traded for security. The leaders who promise these are the ones the people follow. The security they seek and demand is security against want, hardship, and illness. That is the negative way of saying that they demand assurance of shelter, food, clothing, recreation, and medical care without much regard to their ability to earn them."¹

The "Beveridge Report" seems, on examination, not to be quite the "revolutionary" document which was anticipated.³ At Oxford Town Hall, its author is reported to have said on December 6, in part:

"If we have mass unemployment we may not be able to carry out the proposals of my report. . . . I simply won't believe it is impossible to abolish mass unemployment, yet I do not know how it is to be done and do not even know whether anyone else does."

Fair enough; neither do we.

"The Australian Labor Government's plan for social security after the war is similar to Sir William Beveridge's, but is much more comprehensive. It is estimated it will cost £50,000,000 to £60,000,000 yearly, according to the range of benefits finally included, and will provide maternity allowance, child endowment, widows' pensions, health and unemployment insurance, free hospital and medical services irrespective of income, old-age pensions without a means test much larger than those now paid, and a living allowance on a family basis probably

* This is the second editorial of a series.

equal to the present basic wage of about £4 10s. weekly during unemployment.

"A government spokesman said the aim would be to provide security from the cradle to the grave.

"The health plan will involve the zoning of Australia into medical districts and the employment of 2,000 doctors and thousands of nurses and salaried staffs of hospitals and health centers. It is suggested that doctors demobilized from the fighting forces might be absorbed into this scheme.

"The Commonwealth may take over public hospitals, now a responsibility of the States. Doctors' salaries would range from £800 for junior general practitioners to £1,650 for senior physicians and surgeons. There would be more than 450 new one-man health centers throughout the Commonwealth.

"Cities also would be zoned, Sydney having thirty-five health centers; Melbourne, 25. Infant health centers and convalescent and rest centers would also form part of the scheme."

Just how all this is to be accomplished in face of the mass unemployment which, if history repeats itself, is to be anticipated after the war we haven't an idea.

We do know that here in the State of New York,⁵ the public medical-care program laid down by practical, hard-headed representatives of the Medical Society of the State of New York and the State Department of Social Welfare* in some respects right now goes farther than the projected medical service plans of either Sir William Beveridge or the Australian Labor Government. To quote Lee C. Dowling, Deputy Commissioner for Public Assistance of the State Department of Social Welfare, in part: "That this was done without regimented socialization of private medicine, without injury to the doctor-patient relationship, without adversely affecting the economics of private practice—and with a measurable improvement in the quality, quantity, and efficiency of medical services—is a singular achievement. . . . Further, . . . this plan comprises a partnership of government and the medical profession functioning cooperatively in the interests of the public health and welfare. . . ."

Medical care⁶ is construed to include necessary preventive, diagnostic, cor-

rective, and curative services, and supplies essential thereto, provided by qualified medical and related personnel for conditions in a person that cause acute suffering, endanger life, result in illness or infirmity, interfere with his capacity for normal activities, or threaten some significant handicap. In the provision of such medical care, full and proper use shall be made of existing public and private medical and health services and facilities.

The medical care plan provides for (a) local medical direction and administration for a clearly defined local program, (b) medical and social coordination, with suitable medical and fiscal record-keeping, and (c) integration with community medical and health resources. The pattern for providing the items of medical care listed below may include any combination of the following:

- (a) Free choice of physician and fee-for-service system
- (b) A salaried system rotating or fixed according to circumstances
- (c) A rotating panel system
- (d) Specialists' services and hospital care according to approved local practices

The local plan in New York State may provide for all forms of medical care including—*regardless of the extent of State participation*—many or all of the following:

Acute illness, home or office
Ambulance service
Boarding homes for invalids
Chronic illness, home, office, etc.
Clinic care, by referral
Consultant services
Dental care, including
 Prophylaxis
 Treatment
 Fillings
 Extractions
 Dental surgery
 Dentures
Drugs, serums, etc.
Eye examinations
Eyeglasses and glass eyes
Fractures
Hospital care
Laboratory services

Major surgery, home or hospital
 Medical services in hospital
 Minor surgery
 Nursing care, including
 Visiting nurse, per visit
 Registered nurse, per day
 Practical nurse, per day
 Home medical aids
 Nursing-home care
 Obstetrics, home or hospital
 Physiotherapy
 Pneumonia treatment
 Preventive services, by referral
 Prosthetic or surgical appliances
 Radium treatment
 Sickroom supplies
 Specialist services
 Tuberculosis treatment, home
 Venereal disease treatment
 X-ray diagnosis
 X-ray treatment

We recommend to all who are interested in the medical care aspects of social security the method of procedure followed in the State of New York⁵ so clearly set forth by Mr. Dowling; namely,

building from the ground up, not from the top down. The method has this advantage: it works with a minimum of bureaucratic control; it is founded on well-understood principles; it works in times of peace; it does not require a state of war to assure its continuance; it operates within the framework of reality as a partnership; it "indicates that the medical profession can work with government agencies without surrendering its own freedom of action or lowering its standards of service. . . . It may avert the evils of State Medicine."⁷

Medical Licensure

The Federation of State Medical Licensing Boards has upon its shoulders at the present time a great responsibility.

The current wartime problem of the redistribution of physicians brings up for study the whole structure of medical licensure and education. "Some thousands of physicians," says the *J.A.M.A.*,¹ "have already indicated to the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians their willingness to be 'dislocated' for the duration of the emergency to meet the needs of the civilian population." A survey of the laws regulating the licensing of physicians in various states has been undertaken by the Federation with a view to the adoption at the earliest possible time of new laws or modifications of existing regulations with the purpose of meet-

ing the speeded process of medical education.

"Clearly," says the *J.A.M.A.*, "the processes of licensure must be geared to meet this emergency." Administratively, much can be done to meet the situation. It has been suggested that the granting of temporary permits to practice on an interstate basis for the period of the emergency might be a means of meeting one of the most crucial problems; namely, the relocation of physicians to meet industrial and civilian needs. It has been reported that the Attorney General of the United States has suggested that licensure laws might be invalidated for the period of the emergency, also that state legislatures might immediately pass enabling legislation for such invalidation. Since the legislatures of forty-four states will meet in 1943, additional legislation might well be considered at this time.

A word of caution seems necessary.

¹ *J.A.M.A.* 120: No. 12: 925 (Nov. 21) 1942.

At this writing² the Army and Navy have just announced their plans to mobilize 200 to 300 colleges and universities for training men in the armed forces. The significance of this procedure on American liberal education will undoubtedly be profound, and its consequences with respect to medical education will be disturbing, to say the least. No one expects that we shall come through this war without scars. But the standards of premedical and medical education and practice cannot be too greatly modified without, in our opinion, appalling disservice to the living and to the national war effort. Unless one visualizes medicine as merely a technical study in the delay of death and not as a contributor to the art of living, standards of practice and of learning do matter.

"Several efforts," says the J.A.M.A.,¹ "have been attempted to break down the standards of medical education and medical care and to bring into the practice of medicine half-educated physicians. . . ." We do not believe that the good common sense of responsible administrators backed up by the sound horse sense of the American people whose very lives and health are at stake would tolerate for long any such efforts at a time when our national existence is under serious extraneous threat. We could not conceive of any subtler sort of sabotage of our domestic health and morale. It is, of course, possible that certain minority groups may attempt to use the dislocations and changes which are the inevitable concomitants and consequences of a total war for their own ends. In so far as these ends are not in the actual public interest, we do not believe they will prevail.

As evidence of the sound common sense of the Federation of State Medical Boards, we list below the principles underlying proposed legislation to authorize and provide for the temporary admission to practice of physicians and dentists during the war emergency. These principles were derived from a joint meeting of the F.S.M.B. and the P.A.S.:

STATEMENT OF PRINCIPLES TO BE RECOMMENDED TO THE RESPECTIVE STATE BOARDS OF REGISTRATION AND EDUCATION IN MEDICINE AND DENTISTRY

1. The need for relocation or assignment of physicians or dentists shall be determined by the Directing Board of the Procurement and Assignment Service with the aid of the State Committees of the Procurement and Assignment Service and other agencies and on agreement with the State Boards of Registration and Education in Medicine and Dentistry.
2. These needs shall be met as far as possible by the relocation of physicians or dentists holding licenses *within the State*.
3. Whenever possible, needs shall be met by taking full advantage of *existing provisions for reciprocity between the states and interstate endorsement*.
4. Whenever existing laws make impossible the granting of temporary certificates, state boards should recommend to the Governor and to the state legislatures the earliest possible enactment of the bill designed to make possible the utilization of physicians and dentists under *temporary certification*.
5. When existing measures for relocation of physicians or dentists prove inadequate, State Boards of Registration and Education may request the Directing Board of the Procurement and Assignment Service to certify to them the names and qualifications of physicians and dentists who have volunteered or who may be otherwise available for relocation, at which time also such physicians or dentists may be notified that their names have been sent to the State Boards making such requests.
6. The physician or dentist who accepts relocation shall agree to assignment to *the specific area in which services are required* and to acceptance of a certificate which *limits the duration of such service* to the period of the emergency and for such additional time as the State Boards may prescribe.
7. In view of the emergency character of this action, the Committee representatives, the Directing Board of the Procurement and Assignment Service, and the Federation of State Medical Boards of the United States recommend that fees for such certification be waived or reduced to a minimum.

This seems to be a practical approach to the instant needs of the country for medical service. We do not doubt that a similar practical approach will be made to the problem of premedical and medical education, at the moment seemingly threatened by military necessity.

¹ December 18, 1942.

Diabetic Coma

Diabetic coma is frequently, though not invariably, preventable. When it is present, prompt, skillful treatment should, with few exceptions, avert disaster. It is highly instructive, therefore, to study the factors that precipitate diabetic coma, and to analyze the causes of death therefrom.^{1,2,3}

Analysis reveals that infection is the precipitating factor in the majority of diabetic comas, while dietary infractions and insufficient insulin are responsible for about 25 per cent. Coma is the mode of onset in 5 per cent of diabetics, previously unaware that they were afflicted with this disease. Infection is the precipitating factor in such cases. It is the interesting and important contention of leading authorities in the field of metabolism that excessive carbohydrate ingestion is not a prime factor in the mechanism of diabetic acidosis.^{4,1} The female diabetic is twice as subject to attacks of coma as is the male. This has been ascribed to the pubertal and climacteric changes of the female.

The great majority of deaths from diabetic coma are due to shock or to the associated complicating disease. About 36 per cent of the mortality can be attributed to shock alone, even if infection is present. In the absence of infection—chiefly pneumonia and sepsis—shock is a cause of death in 75 per cent of the cases. This clearly indicates the line of treatment, the measures that should be taken to overcome shock, and the specific therapy which the underlying infection demands.

Criteria in appraising the prognosis of diabetic coma can be divided into major and minor. Advanced age of the patient, low blood pressure, and the severity of the under-

lying infection are the criteria that determine the outcome. Blood pressure below 80 mm. is an ominous sign. Factors of lesser importance are the duration of the coma, elevated blood sugar, and azotemia. Carbon dioxide combining power, per se, is not a valuable mortality index. If the coma is untreated for more than forty-eight hours, chances for survival are greatly reduced. Marked azotemia is always associated with, and is in part due to, severe shock. No single factor is an infallible, prognostic index, but all the factors enumerated, properly evaluated, determine the prognosis.

The lesson is plain. It is axiomatic that the diabetic patient must adhere to the schedule of his diet and insulin needs. Respiratory infections should be avoided as the plague. Skin and other infections call for immediate medical attention to avert septic complications, by chemotherapy or other appropriate measures. Once coma has supervened, no time must be lost. Fluid and salt requirements to restore the depleted blood volume should be quickly administered and the insulin requirements re-evaluated in the altered situation. The general treatment of shock should be promptly instituted. If the diabetic is educated along these lines as well as in the rules of diet and insulin action, coma will occur less frequently, and if unavoidable, will be treated with happier results.

Conditioned Blood Transfusions

The universal and frequent use of blood, plasma, and blood substitutes for shock, hemorrhage, dehydration, and other conditions characterized by depleted blood volume is the best testimony of their efficacy. In the case of plasma and blood substitutes, it is a simple matter to have the vital material on hand for immediate use, even in areas remote from centers of civilization. This does not hold true for blood; yet in cases of serious hemor-

rhage blood transfusion may be the only life-saving measure. Even if a blood bank and laboratory facilities are available, the time consumed in typing and cross-matching may mean, in instances of severe trauma or massive hemorrhage, the difference between life and death. In order to circumvent this deficiency, the blood of so-called universal donors, members of group O, has been modified or conditioned by an ingenious method¹ so that such

blood may safely be used in transfusions on the spot, without typing, or matching, with the blood of the recipient. This conditioned blood can be preserved, as in a blood bank, in the most remote areas, means of refrigeration being the only requirement.

The problem of conditioning group O blood for safe universal transfusion is the reduction or elimination from the donor blood of the anti-A and anti-B isoantibodies. This is accomplished by the addition of the blood group specific substances A and B to the collected O blood. The pure A and B substances are injected in measured amounts into O blood which has been collected into a vacuum container.¹ It has been demonstrated that this addition virtually neutralizes the undesirable and potentially dangerous isoantibodies. Of 176 transfusions by this method given to 147 patients,² there were no instances of hemolysis or agglutination with icterus and hemoglobinuria. In only 10 transfusions were there

fever and chills, a percentage which is of the same order as that encountered in transfusions with carefully matched blood, and cannot be attributed to these hemolytic isoantibodies.

It is not intended that conditioned blood transfusions should supplant the usual careful routine typing and cross-matching of bloods when time and facilities permit of such laboratory technic. For the grave emergency, however, where every minute is vitally precious, an apparently safe and tried method of transfusion is offered for immediate use. It may hereafter be highly advisable to have conditioned blood as part of a blood bank, for the extreme emergency, or as the sole blood to be used in isolated regions, such as remote battle lines.

A letter from the Office for Emergency Management, War Manpower Commission, in Washington, D.C., was published on page 28 of the January 1 issue of the JOURNAL. The important part of the letter is reprinted below:

"It is of the utmost importance that the Procurement and Assignment Service for Physicians, Dentists, and Veterinarians, immediately have the name of any doctor who really is willing to be dislocated for service, either in industry or in overpopulated areas, and who has not been declared essential to his present locality. This is necessary if the medical profession is to be able to meet these needs adequately and promptly. We urgently request that any physician over the age of 45 who wishes to participate in the war effort send in his name to the State Chairman for the Procurement and Assignment Service in his state."

"Sincerely yours,

FRANK H. LAHEY, M.D., Chairman, Directing Board
Procurement and Assignment Service for Physi-
cians, Dentists, and Veterinarians"

Special Article

STATUS OF FOREIGN PHYSICIANS*

THIS abstract is a report to the membership of the State Society made after six months' study of the status of the foreign physician. Some of this material may be already known to you.

To familiarize you with the action leading to this study it would be well to give the background of action taken by the House of Delegates at its annual meeting in New York in April, 1942. The members passed a resolution requesting the Council of this Society to make a study of the status, present and future, of the noncitizen physician.

In May a Committee was appointed and was directed through the resolution to—

1. Make a study of the present and possibly the contingent future problem confronting the public and the medical profession.

2. Formulate a plan

- (a) "Taking into consideration the protection of the public."

- (b) "For the preservation of the standards of the medical profession."

- (c) "The safeguarding of the rights and legal interests of the members of that profession."

- (d) "With humane consideration of the situation of the emigre non-citizen physician."

3. "Present the report of such studies and their recommendations for the solution thereof and the means for its accomplishment, both present and future, at the next meeting of this House of Delegates."

4. "That the Council take such steps in the interim between this and the next meeting of this House of Delegates to properly safeguard the medical interests of the armed forces of the United States, the State of New York, the public health and welfare, and the existing standards of the profession of medicine."

It is advisable to note that factual relationships to licensure and to commissions for foreign physicians frequently change. The Committee will endeavor to keep the Council and the members informed of these changes as promptly as possible.

* Members of the Council Committee to Study the Present and Future Status of Foreign Physicians are Howard Fox, M.D., New York City, David A. Haller, M.D., Rochester; and F. Leslie Sullivan, M.D., Scotia, chairman.

The Committee determined that its policy is to improve the educational standards in relation to all applicants for admission to practice; second, that we are not concerned at present with the limitation of the number of doctors; third, that the work of the Committee relates to foreign applicants of all countries without discrimination as to race or creed.

In studying the annual report on medical licensure† and allied statistics by the Council on Medical Education and Hospitals of the American Medical Association, the Committee gives you the following data:

"For a period of twelve years beginning in 1926 the credentials of physicians coming from abroad have been verified by official correspondence with the medical school, either directly or through the diplomatic services. This has been impossible for the last several years, and on the licensing boards in the various states rests the responsibility of determining the authenticity of the evaluation of credentials presented from schools outside the United States and Canada."

"More than half of the examining and certifying boards obtain from the Council verification of biographic data and other claims before granting a license or permission to take the licensing examination."

"New York does not, however, obtain from the Council verification of data or other claims before granting a license or permission to take the examination. This decision rests with the New York State Department of Education."

"During the year 1941 there were 8,758 licenses issued to practice medicine and surgery in the forty-eight states, the District of Columbia, Alaska, Hawaii, Puerto Rico, and the Virgin Islands. Of the 8,758 licenses, 6,020 were issued after examination and 2,738 by reciprocity and endorsement."

"The greatest number of licenses during 1941 were issued in New York—1,173; California granted 630; Illinois, 581; and Pennsylvania, 539. These were the only states which registered more than 500. Twenty-two states and the territories and possessions issued licenses to fewer than 100. The fewest number (15) were issued in South Dakota."

† Medical Licensure Statistics for 1941, J.A.M.A. 119: 141 (May 9), 1942.

TABLE 1.—LICENTIATES REPRESENTING ADDITIONS TO THE MEDICAL PROFESSION, 1941

	Examination	Reciprocity and Endorsement	Total
California	347	6	353
Illinois	438	11	449
New York	804	189	993
Pennsylvania	385	14	399

Nevada licensed 16 and Delaware 22. An interesting point to observe is the fact that in some states the number registered without examination far exceeded those required to write an examination, while on the other hand in many states the reverse was the case. The latter is particularly significant in New York, where 886 took examinations and 287 received licenses by endorsement of their credentials. Louisiana issued only 12 of its 157 licenses on the basis of credentials only. Three were registered in the Virgin Islands, 11 in Alaska, 14 in Puerto Rico, and 31 in Hawaii. Of these, 21 were granted certificates by endorsement of credentials: 5 in Alaska, 13 in Hawaii, and 3 in the Virgin Islands. *The states of Florida and Idaho grant licenses only on the basis of examination. Massachusetts, Rhode Island, and Hawaii have no reciprocity agreements but endorse diplomates of the National Board of Medical Examiners.*"

"Since 1937, fewer licenses have been issued annually. In 1941 there were 395 fewer licenses issued than in 1940 and 1,075 fewer than in 1937. The increase in that year, of over 800 more than in 1936, represented largely physicians migrating to this country from Europe."

"Licenses issued do not, however, represent individuals, since several have been licensed in more than one state during the year. Nor does the total represent additions to the medical profession at large, since those licensed by reciprocity and endorsement, with the exception of the National Board of Medical Examiners, have previously been registered."

"There were 5,206 graduates of approved medical schools in the United States examined, of whom 4.6 per cent failed; 167 graduates of approved Canadian schools, 15 per cent of whom failed; 1,708 graduates of schools outside the United States and Canada, principally in Europe, with 59.6 per cent failures; 8 who graduated from medical schools now extinct, of whom 50 per cent failed; and 422 from unapproved and osteopathic schools, of whom 46 per cent failed."

"The total number examined (7,511) do not represent individuals, since a candidate might

TABLE 2.—SOURCE OF CANDIDATES EXAMINED, 1941

take the examination in more than one state and would be counted in each state. This applies to those who pass or fail, or those who fail and later pass in one or more states, or pass in one or more states and later in the same year fail elsewhere. However, if a candidate fails more than once in a given state within the year, he is counted in that state only once as a failure."

"The source of candidates for licensure last year are further tabulated in Table 2, giving totals for five groups—namely, approved medical schools in the United States and in Canada, schools no longer in existence, schools of foreign countries, and unapproved institutions. Of the United States schools 4.6 per cent failed, and of the graduates of Canadian schools 15 per cent. The greatest percentage of failures represented two groups, foreign schools and unapproved schools. In these two groups 59.6 and 46 per cent, respectively, failed. Half of the 8 graduates of schools now extinct failed."

"One hundred and sixty-seven graduates of nine approved medical schools in Canada took the test for medical licensure in the United States in 1941 in thirty states, the District of Columbia, and Hawaii, of whom 142 passed and 25 failed. The greatest number (60) represented McGill University Faculty of Medicine, who were examined in twenty-two states, and 45 graduates of the University of Toronto Faculty of Medicine in seventeen states, while 17 from Dalhousie University Faculty of Medicine applied for licensure in three states. The highest percentage of failures was 80, representing 5 graduates from the University of Montreal Faculty of Medicine examined in four states, only one of whom was successful. The State of New York examined 42 Canadian graduates; California, 23; Minnesota, 12; and Pennsylvania, 11. All other states testing Canadian graduates examined fewer than 10, and nineteen states and Hawaii fewer than 5. Seventeen of the total number of failures (25) were unsuccessful in the examination of the New York Board of Medical Examiners."

TABLE 3.—GRADUATES OF MEDICAL SCHOOLS IN CANADA EXAMINED FOR LICENSURE IN THE UNITED STATES, 1941

	Examined	Passed	Failed
California	23	23	0
Illinois	7	6	1
New York	42	25	17
Pennsylvania	11	11	0

"Twenty states examined 1,708 graduates of medical schools other than those in the United States and Canada. One took the test in Alaska and 4 in Puerto Rico. In 1941 also 422 unapproved graduates were examined in four states and Hawaii."

"Forty-three candidates were examined in Alaska, Hawaii, and Puerto Rico, 37 of whom passed, and 6 of whom failed. Of these, 19 were tested in Hawaii, with one failure; 18 in Puerto Rico, with 5 failures; and 6 were examined in Alaska and passed."

"Altogether in 1941 there were 7,511 examined, of whom 6,030 passed and 1,481, or 19.7 per cent, failed."

"The number so examined in 1941 was a decrease of 410 from the number examined in 1940; likewise a decrease of 252 among successful returns and a decrease of 158 among those who failed. The number of graduates of foreign medical schools examined in 1941 was considerably fewer than in previous years."

In Tables 4 and 5 attention is drawn to the figures for the states selected in Table 5.

Of the total number (190) from foreign faculties examined in the United States, 101 passed and 89 failed. The percentage that failed was 46.8; the number of examining boards was 13.

"From the nine approved medical schools in Canada which offer the complete course, 104 were examined. There were 190 recent graduates of medical schools of countries other than the United States and Canada, and 275 graduates of unapproved schools."

"Combined totals for the graduates of the three years for each of these groups including the number examined, passed, and failed, are given in Table 4."

"Of the graduates of medical schools in the United States, 3.9 per cent failed, with the graduates of Canadian schools showing 14.4 per cent failure, those holding foreign diplomas 46.8 per cent, and graduates of unapproved schools 37.5 per cent."

Failures Before Medical Examining Boards by Licentiatees

"Seventeen states licensed in 1941 only physicians who had never failed a state board

TABLE 4.—SOURCE OF GRADUATES OF 1939, 1940, AND 1941—EXAMINED, 1941

New York	69	70
Pennsylvania	1	3

examination, while New York licensed 417 who had failed previously. With the exception of California, Illinois, Massachusetts, New Jersey, Ohio, and Pennsylvania, no state licensed more than 8 such candidates."

"In the computation of these statistics, it was noted that 57 licentiatees had failed five or more times. Of these, 22 had five failures before obtaining a license, 10 had six, 9 had failed seven examinations, 3 individuals had failed eight and nine times, 2 failed ten, 2 failed eleven, and 2 failed fourteen tests. Noteworthy were 4 candidates from unapproved medical schools licensed in Massachusetts, one each after sixteen, seventeen, twenty-three, and twenty-five unsuccessful attempts. The great majority of these physicians were Massachusetts and New York examinees. There was one graduate of an approved school in the United States who made fourteen attempts in New York before registration."

"The number of physicians granted licenses in 1941 to practice medicine and surgery without examination on presentation of satisfactory credentials is given in Table 6. There were 2,729 so registered who presented licenses from other states, the District of Columbia, Canada, and foreign countries, the certificate of the National Board of Medical Examiners, one of the government services, or other credentials."

"The greatest number of licenses granted by this method were issued in New York, where 287 were registered. Seven other states endorsed more than 100 such candidates: California 229, Michigan 188, Ohio 116, Texas 112, Illinois and New Jersey 107, and Massachusetts 100. The largest group representing the same type of credentials were the 714 diplomates of the National Board of Medical

Examiners. Two hundred and fourteen were registered on the basis of such credentials in New York and 100 in Massachusetts."

"One license was granted in New York by endorsement of a license issued in Germany. Two were registered in this state without examination on the basis of a diploma from a European medical school. Eight presented licenses issued in Canada as follows: one each in New York and Wyoming and 2 in Oregon presented licenses issued by the Dominion of Canada, while a physician was certified in Kentucky on a Newfoundland provincial license, another in Tennessee who presented a New Brunswick credential, and in New York 2 were registered on provincial licenses—namely, Ontario and Quebec."

"Of the 2,738 candidates licensed by reciprocity and endorsement, 2,559 were gradu-

ates of approved medical schools in the United States, 56 of seven schools so approved in Canada, 52 graduates of foreign faculties of medicine, 53 of institutions now extinct, and 9 each from unapproved and osteopathic schools."

Licentiates Representing Additions to the Medical Profession

"There were 5,681 additions to the medical profession in 1941. The number removed by death annually approximates 3,700. It would appear that the physician population in 1941 was increased therefore by about 1,900. While it cannot be said that all of those licensed are in practice, it may be assumed that the great majority are. The greatest number in any one state were added in New York—993; and 449 in Illinois. More than 300 received their first license in California and Pennsylvania."

"From the United States schools there were added to the profession by examination 4,290 graduates and 448 by reciprocity or endorsement, a total of 4,738; from the Canadian schools, 90; by examination, 85; and without examination, 5. There were 626 graduates of foreign faculties of medicine, 226 from unapproved schools and from a school now extinct."

"Altogether there were 5,213 graduates of all schools added to the medical profession in 1941 by examination for licensure and 468 by reciprocity and endorsement, a total of 5,681. The number of living physicians in the United States in 1941 was approximately 180,871."

With but four exceptions—namely California, Massachusetts, Nebraska, and Connecticut—the state licensing boards specify two years or more of college as a preliminary requirement. It is to be noted that New York is among the states requiring two years or more of preliminary training—that is, pre-medical study.

Quoting from Handbook 9 of the University of the State of New York: "Effective September 1, 1942, the required two years of college study shall include approved courses in English, physics, and biology, covering at least one academic year each; and approved courses in chemistry, covering at least one and one-half

academic years, including an approved course in organic chemistry. Approved courses covering one academic year shall in each case be substantially equivalent to six semester credit hours. (Regulations, approved December 20, 1935, and amended December 20, 1940.)"

Required Hospital Internships

New York State is not listed in Table 9. However, New York State does require satisfactory evidence of completion of internship of graduates of medical faculties abroad, "leading to and requisite for the license to practice medicine in the country where such medical school is located. The requirement that such examination be passed and that such internship be completed may be waived by the Commissioner and the applicant admitted to the examination, providing that the applicant submits satisfactory evidence that failure to pass the examination and complete the internship was due to circumstances outside his control and which arose out of international emergencies. This does not affect students who began their medical education in Europe prior to March 1, 1933," or about the time of the invasion of Austria. The quotation is from Handbook 9, 1942, of the University of the State of New York. This regulation was passed after the first World War because graduates of extramural schools of Scotland and certain schools in Italy and other countries could not get back to take their State License examinations or could not furnish proof of their internship in the country in which they were studying. Of course at this time the license feature works both ways, for Americans as well as foreigners.

The medical licensing boards of twenty states, the District of Columbia, Alaska, Hawaii, and Puerto Rico require that all applicants for licensure serve a hospital internship.

Candidates Examined

"The number of candidates examined in the United States, its territories, and possessions in the five-year period 1937-1941 are given in Table 10. For each year there is recorded the number who passed and failed licensing examinations. Totals for the five-year period and the percentage of candidates who failed are also given."

"During this period 37,985 were tested, of whom 32,006 were successful, and 5,979, or 15.7 per cent, failed. Of these, 3,414 were examined in New York and passed, 2,517 in Illinois, 2,513 in Pennsylvania, and 1,930 in California. More than 1,000 were successful also in Massachusetts, Michigan, Minnesota, New Jersey, and Ohio. Nine states examined and passed between 500 and 1,000 applicants for licensure, thirty states and the District of Columbia registered fewer than 500, and in ten of these fewer than 100. The smallest number, 8, passed examinations in New Mexico."

"The percentage of failures in all states and the territories and possessions has increased from 10 per cent in 1937 to 20.6 per cent in 1940. The number failing in 1941 was 19.7 per cent."

"The greatest percentage of failures occurred in Massachusetts, which had an average of 48.2. The high percentage in that state is due to the fact that by law the licensing board

* Refer to chart of "Reciprocity and Endorsement Policies" for further data. (See page 131.)

1 Certificate of National Board of Medical Examiners and licensure in country in which school of graduation is located.

2 Internship or one year in medical school in United States.

3 Certificate of National Board of Medical Examiners.

4 For graduates of last five years: if more than five years, \$50.

5 Residence of one year in Delaware.

6 Provided similar privileges are accorded licentiates of District of Columbia by licensing agency of the jurisdiction from which the applicant comes.

7 Senior year in class A medical school in United States.

8 No applications accepted after Feb. 21, 1941.

9 Enemy aliens not accepted.

10 Application must be filed six months prior to date of examination.

11 Licensed to practice medicine and surgery in country in which school of graduation is located; otherwise required to complete senior year in approved medical school in United States.

12 Diplomates of National Board of Medical Examiners eligible.

13 License to practice medicine and surgery in the country in which the school of graduation is located.

14 Internship and one year graduate work.

15 Diplomates of the National Board of Medical Examiners exempt from special requirements.

16 Internship and graduate work.

17 Internship completed in foreign countries after July 1, 1934 not acceptable.

18 Rotating internship in approved hospital in the United States or completion of senior year in class A medical school in the United States.

19 These requirements apply also to graduates of Canadian schools.

20 Graduates from foreign medical colleges accepted if they present also a diploma from an approved medical school in the United States.

21 Provided standard was the same as California's on the same date.

22 Degree from an American medical school. Medical Council of Delaware required.

23 Diplomates of the National Board.

24 Very limited number contracting to be accepted.

is required to admit to its examination the graduates of unapproved schools, the majority of whom repeatedly fail. New York had a failure percentage of 40.5, occasioned in part by the admittance to examination of a large number of graduates of foreign faculties of medicine, who likewise repeatedly failed. On the other hand, twenty-eight states failed less than 5 per cent; in twelve of these the percentage of failures was less than one. In five years seven states—Arkansas, Nebraska, North Carolina, Oklahoma, Oregon, Utah, and Wisconsin—had no failures."

"These figures represent examinations given, and not individuals. A candidate who fails more than once in a state in a given year is counted as only one failure, but should he fail in one of the succeeding years he is counted in that year also. The same is true of the successful candidates. Table 10 is merely a compilation of figures computed annually and grouped for comparison. Nevertheless, it gives a fair approximation of the number of physicians added to the profession in five years by means of written examination."

"With the migration of physicians to this country, beginning in 1936, and their failure to pass examinations, the percentage of failures began to rise until it reached a peak of 20.7 in 1940. In 1941 it dropped 1 per cent for the country as a whole in spite of the high percentage of failures in New York State. The rise in failure percentages has also been due to the inability of graduates of unapproved medical schools to obtain licensure successfully without failure."

"Graduates of Approved Schools and Others Registered, 1922-1941"

"In 1928 the classification A, B, and C by the Council was discontinued and medical schools have since been classified as approved or unapproved."

"Of the 8,768 registered by all methods in 1941, 7,727, or 88.1 per cent, represented graduates of approved medical schools, and 1,041, or 11.9 per cent, the group designated as 'others.'"

"Of the 8,768 registered in 1941 there were 5,112 who were graduates of approved medical schools of the United States and Canada, licensed by examination, and 2,615 licensed without examination. By examination, 221 unapproved graduates and 697 foreign graduates were registered. Likewise among those registered by endorsement there were 24 graduates of unapproved schools and 99 foreign graduates."

"New York registered 735 graduates of approved schools of a total of 1,175 registered. This state licensed the largest number with foreign credentials—439. Only graduates of approved schools in the United States and Canada were registered in Kansas, Minnesota, Nebraska, Nevada, North Dakota, South Carolina, and South Dakota."

Physicians Examined on Basis of Credentials Obtained in Countries Other than the United States and Canada

"The requirements of candidates for medical licensure in the United States, Alaska, Hawaii, and Puerto Rico on the basis of credentials obtained in countries other than the United States and Canada, based on data recently received from state boards of medical examiners, are given in Table 11. Eighteen states report that, because of the inability to evaluate foreign credentials, holders of such certificates are not eligible for licensure, while one state reported that no new applications have been accepted since February 21, 1941. Seventeen states, Alaska, Hawaii, and Puerto Rico require full citizenship, and ten states require first naturalization papers as a condition precedent to taking the examination. *In some states the requirement is by rule of the medical board; in others the provision is by statute. In addition, other restrictions are imposed.* Ten states which accept foreign graduates require a certificate in the basic sciences. Sixteen states, Alaska, Hawaii, and Puerto Rico require a one-year internship in a United States Hospital approved for intern training. In five states there is a requirement of a senior year's work in an approved medical school in the United States. In four states these graduates are not acceptable unless they can present a license to practice medicine and surgery in the country in which the school of graduation is located. In one state a limited number contracting to practice in rural districts may be accepted, while another reports that enemy aliens are not considered."

For comparative study the Committee chose what they considered to be a model cross section of the United States in regard to the requirements of certain states for foreign physicians to be admitted to examination in that particular state. The states chosen were:

1. New York State—Licensed 70 per cent of the total number of foreign physicians admitted to practice in the United States in 1941.

2. California—Fourth largest number licensed.

3. Pennsylvania—Admitted 13; ninth largest number licensed.

4. Texas—Licensed 5 or less.

5. Kansas—Admitted none.

6. North Carolina—Admitted none.

In examining laws in regard to medical practice of the various states chosen, the following information is available:

New York State—see Table 11. In this table are listed the requirements for medical licensure on the basis of credentials obtained in countries other than the United States and Canada. Note that first citizenship papers are required in New York State.

California—In addition to usual pre-medical and medical studies, it is required under Section 2193, C, D, E:

C. "He has been admitted or licensed to practice medicine and surgery in the country wherein is located the institution in which he has completed the residence courses of professional instruction required under this chapter."

D. "He has completed either the senior or fourth or final year in an approved medical school in the United States, or, in lieu of this, he has served at least one year in residence in a hospital located in the United States and has been approved by the board for training of interns."

E. "If the applicant is not a citizen of the United States, the country in which he has been licensed to practice medicine and surgery will admit to practice therein citizens of the United States upon proof of prior admission to practice medicine and surgery in some state of the United States or upon proof of matters similar to those required in this section for graduates of foreign medical schools. Subdivision E does not apply to any person who on March 31, 1941, was registered as an intern under Chapter 5 of Division 2 of the Business and Professions Code, relating to the practice of medicine (as amended, Laws of 1941, Ch. 751)."

No other limitations, rules, or regulations are mentioned except those in Table 11 of this report.

Pennsylvania—Requires internship in approved United States hospital.

Texas—Article 4500—"May endorse license if citizen is a graduate of reputable medical college ("reputable" meaning one eligible for examination by Board of Medical Examiners). Board shall not grant license to applicant who does not hold license issued by another state, territory, or district of the United States."

Article 4500 A—"Foreign nations, Reciprocal

Arrangements with: The Board of Medical Examiners shall not, under the provisions of Article 4500, grant a license to practice medicine to any applicant whose authority to practice medicine in any other nation or country was granted by a nation or country in which a similar law in reference to granting license to practice medicine under a reciprocal arrangement does not exist in favor of physicians of this State (Laws of 1939, p. 352)."

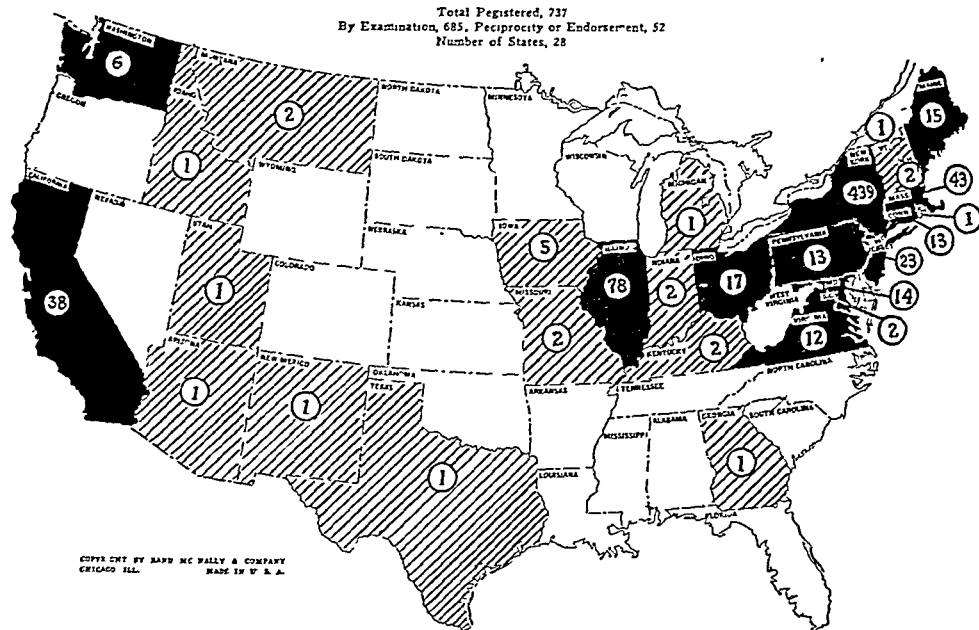

Kansas—Citizenship required. Physicians must be licensed to practice medicine in country where school of graduate is located, or must complete senior year of an approved United States medical college.

North Carolina—Board of Medical Examiners are appointed by the North Carolina Medical Society, Inc. See 6607, Code of 1939, Ch. 110, Laws of 1941, Ch. 163.

"In the figures regarding physicians examined on the basis of credentials obtained in countries other than the United States and Canada by licensing boards of the United States, Alaska, and Puerto Rico, they represent both American and foreign-born physicians educated abroad. Since 1930, and until the issuance of passports was terminated by the Department of State, students from the United States migrated to Europe to obtain medical education. It is estimated that 2,000 were studying in Europe. Many were able to complete their training and returned to the United States to practice. Many of those licensed in recent years represent foreign-born physicians. One hundred and four faculties of medicine, including four licensing corporations, of nineteen European and five other countries were represented. There were 1,708 examined by twenty states, Alaska, and Puerto Rico, of whom 690 passed and 1,018, or 59.6 per cent, failed. Graduates of the University of Vienna represented the largest group—479—who were examined in fourteen states with a percentage of failures of 57. Ten states examined 139 graduates of the University of Berlin, of whom 60.4 per cent failed. Graduates of all other schools were examined in fewer than ten states. The greatest number examined by any one state (1,207) were in New York," or 70.67 per cent of the total number examined in the United States, of whom 426 passed and 64.7 per cent failed. Massachusetts examined 139, of whom 102, or 73.4 per cent, failed. Illinois examined 119, of whom 34.5 per cent failed. More than 25 were examined in 1941 in California, Connecticut, and New Jersey. Of these states, Connecticut had the highest percentage of failures

CHART — STATES REGISTERING GRADUATES OF MEDICAL FACULTIES ABROAD, 1941

Total Registered, 737
By Examination, 685, Reciprocity or Endorsement, 52
Number of States, 28

The states in black registered more than 5 such candidates, those shaded 5 or less.

CHART 1.

—68.3. Seven states examined one each, 6 of whom were successful.”

“Chart 1 shows in graphic form the number registered during 1941 by states examining graduates of foreign faculties of medicine. Included in the chart are 52 who were granted licenses without examination, with but 3 exceptions, on the basis of a license obtained in the United States. The states which licensed more than 5 graduates are indicated by states reproduced in black; those shaded, 5 or less.”

“There are assembled figures showing for the five-year period 1936-1940 the number of graduates of faculties of medicine outside the United States and Canada admitted to licensing examinations in this country. Included also is a tabulation for 1941. There were represented one hundred and nineteen European faculties, nine of the licensing corporations of Great Britain, and sixteen schools of other countries.”

“During the five-year period 1936-1940, 6,451 were examined, with 45.2 per cent failures and, in 1941, 1,708 with 59.6 per cent failures.”

“The largest group from any one school examined in the five-year period were 1,318 from the University of Vienna, of whom 45.7 per cent failed. There were 650 from the University of Berlin, with 44.9 per cent

failures. Large numbers also were examined who presented credentials from the universities of Prague, Paris, Freiburg, Frankfort-on-the-Main, Würzburg, Munich, Breslau, Heidelberg, Bologna, Naples, Rome, Basel, Bern, Zurich, Geneva, and Lausanne. Two hundred and eighty-four in the five-year period presented in lieu of the M.D. degree the triple qualification certificate of Scotland. These individuals obtained their education in the so-called extramural schools of Scotland.”

“Statistics record the number of graduates of faculties of medicine abroad examined for medical licensure in the United States in twelve years—1930 to 1941 inclusive. Altogether, 9,588 were examined, of whom 5,093 passed and 46.9 per cent failed. The greatest number, 2,088, were examined in 1940, when 54.7 per cent failed. The number licensed in twelve years increased from 92 in 1930 to 948 in 1940. In 1941, 158 fewer were registered than in 1940. The highest percentage of failures occurred in 1941—59.6. At no time during this twelve-year period did fewer than 30.7 per cent fail.”

“The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. No opportunity is afforded for visiting and inspecting such schools, nor are official reports

received from them. The Council therefore has no evidence on which to base a rating."

The National Board of Medical Examiners, on February 15, 1942, adopted the following drastic resolution relative to examination of foreign physicians:

"Resolved, that, beginning February 15, the National Board of Medical Examiners will not accept applicants for admission to its examinations from graduates of any medical school in continental Europe or from graduates of the extramural schools of Scotland and Ireland."

"This action does not apply to graduates of university schools in the British Isles or to those candidates who had registered before February 15, 1942."

"One of the factors that caused the board to take this action was the refusal of approximately one-half of the states of this country to grant licenses to physicians trained in European medical schools even though they had been certified by the National Board."

Relative to the problem of a commission for foreign physicians, the latest data obtainable is given—"That alien doctors of friendly, neutral, or cobelligerent countries—that is, those countries with government in exile—may be commissioned directly into the army under the following conditions:

1. They must have equivalent premedical and medical education.
2. They must have had a license in their own country.
3. They do not need their first papers.
4. Refugees not having governments in exile or not from friendly or neutral countries must be inducted and then commissioned, provided that they are cleared by the F.B.I. They must furnish affidavits that they have no relatives in belligerent armed forces."

These refugees of the latter group must register with the local boards, and:

1. They must have a certified copy of their medical papers (translated).
2. They must have a certified copy of their license and all papers pertaining thereto.
3. They must have information as to the schools from which they graduated.
4. They must have certified first papers and official certified papers of internship.
5. They must present an affidavit that since arrival in this country they have engaged in no activity detrimental to the United States.

It is pointed out that alien refugees must get their citizenship because they have no country and that state licensure cannot be waived

for a commission except to friendly aliens. It is believed that few of New York's 3,000 licensed emigres will be taken into the Army at the present time. They will not be admitted to practice in essential industry.

Relocation and universal conscription is now under consideration. Under Section 1262 of the State Education Law, entitled "Construction of this article," we quote: "This article shall not be construed to affect or prevent the following: (1) The practice of medicine in this state in obedience to the requirements of the laws of the United States by any commissioned medical officer serving in the United States Army, Navy, or Public Health Service or any physician or surgeon employed in the United States Veterans' Administration while engaged in the performance of the actual duties prescribed for him under the United States statutes."

It will be noted, as construed, that this article allows the United States to send physicians into the State of New York to practice in conformance with instructions issued by the Federal Government. It is believed that other states have similar clauses which would allow relocation of doctors to most all of the states and possessions. It has been brought out that in writing up the Lend Lease Act these features were incorporated to allow physicians operating under a federal law to practice in possessions owned by other governments also.

As previously related, it is noted that last year New York State licensed 737 foreign physicians, or 70 per cent of the total for the entire United States and possessions, including the District of Columbia. There were a total of 5,681 additions to the medical profession in 1941. New York State had 1,173 new licenses, and 993 of this number were additions to the profession, or 17.4 per cent of the total number of additions to the medical profession in 1941. The markedly increased load of examinees who are graduates of foreign faculties is shown in the following table.

Summary of the New York State Medical Licensing Examination (Foreign Schools)—1934-1935 to 1941-1942

	Total	Failed	Failed
			Percentage
1934-35	297	119	40.1%
1935-36	402	159	39.6%
1936-37	571	192	33.6%
1937-38	789	318	40.3%
1938-39	1,211	700	57.8%
1939-40	1,770	1,249	70.5%
1940-41	1,644	1,204	67.2%
1941-42	1,558	963	61.9%

It is to be noted from these figures the gradual increase of candidates from 1933, past the peak of emigration in 1934, to the peak of

examinees in 1940. This great increase is due to two things:

1. That the laws of the State of New York are less stringent than those of most other states.

2. That foreign refugees are coming into New York State from countries, mainly South American, and other states in the Union where they had settled several years before.

It is to be noted also that:

1. Twenty states, including Alaska, Puerto Rico, and Hawaii, require full citizenship in addition to other essentials before examination.

2. Eighteen states will not review any credentials of foreign physicians.

3. In ten states, including New York, they are allowed to take the examination with first papers. Four of these states, in addition, demand an internship in a hospital in the United States.

4. One requires, also, further medical training, such as a senior year in medical school.

Requirements of Foreign Candidates for Medical Licensure in the State of New York

(On the basis of credentials obtained in other countries)

The State of New York does not accept the rulings and biographic data of the Council on Medical Education and Hospitals of the American Medical Association.

The State Education Department obtains its own biographic data and sets its own lists. The credentials are verified by student pass books, statements from the registrar of the school, and the original document or diploma.

The approved foreign faculties are listed on page 35 and 36 of Handbook 9, of the University of the State of New York, which contains laws, rules, and regulations. These give merely "registered schools" of Canada. All other foreign schools are classified as "recognized schools." The applicant from these schools can be recognized only if he was graduated from the school before the Hitler regime, or approximately at the time of the invasion of Austria. There is no official list and the graduates of these schools (1914-1938) are approved only on previous work. *New York State has been more generous than other states in this regard.* Original documents only and not photostats of licenses are acceptable. Four have been licensed on eminence since 1918, although there was a period a few years ago when many were endorsed. All others

licensed without examination up to 1937 were accepted by endorsement. In New York State in 1936 there were 932 examined (all classes) and 558 added by endorsement. The total was 1,517. Of this number, 454 were foreign physicians, of whom 217 were added by examination and 237 by endorsement. Figures for succeeding years are given below.

Year	Endorsement
1937	196
1938	70
1939	25
1940	22
1941	3

The above figures can be explained in this way. Up until the year 1936 emigre physicians could have their licenses endorsed, without examination, under Section 51 of the State Education Law. There were many endorsed and there were in addition many other applicants. It was ruled that those that had previously applied would be handled under the old ruling and, after 1936, those are the figures for the number of foreign licenses endorsed under the old ruling. Previously, some foreign physicians were licensed in the State of New York by endorsement through the National Board of Medical Examiners. These licenses would not be included in the above figures.

The committee feels that the status of the foreign physician is very intimately related to the work of Procurement and Assignment. There were in 1941, 27,712 living doctors in the State of New York. Of this number, about 17,600 are members of the New York State Medical Society. This leaves about 10,000 physicians in the State that are not members of the New York Medical Society, some of whom have graduated from grade A schools and might be liable to military service if they were in the draft age. Many of these men who have either dropped their New York State membership or have not applied are physicians interested in specialties.

As far as your Committee can ascertain from studying available figures, there are approximately 6,000 physicians from foreign faculties in the United States, excluding American graduates of foreign schools. As of January 1, 1942, there were:

In New York State, about 4,250. Of this number 3,141 licensed (85% males).

In New York City,* about 1,800, grouped as follows:

* Figures for New York City cover the five counties, and no break-down is available.

TABLE 12.—NEW YORK STATE EDUCATION DEPARTMENT LICENSES ISSUED TO FOREIGN PHYSICIANS—1932-41, INCLUSIVE

	Examination	Endorsement	Total
1932	85	27	112
1933	89	40	129
1934	110	101	211
1935	178	80	258
1936	248	210	458
1937	379	133	512
1938	622	51	673
1939-40	1,370		349
1941			439
			3,141

(Of this total figure it is not known the exact number that may have left the state to practice elsewhere.)

Licensed and practicing, about	600
Serving internships	325
In other institutional work	458
Unlicensed, not in other groups, about	400

The above data is from information obtained from the Procurement and Assignment Service, the New York State Education Department, the National Committee for Resettlement of Foreign Physicians, and the National Refugee Service (see Table 12).

With the problem arising from the exhaustion of communities by the processing of the nation's physicians for the armed forces and the probable relocation of physicians to supply communities by the Manpower Commission, the need to (1) "maintain a numerical balance of all physicians in the counties, and (2) relieve the shortage of medical personnel in those counties, already exhausted," is readily apparent.

The New York State Medical Society, through this Committee, initiated the move to provide better collaboration and coordination between the office of Procurement and Assignment and the County Medical Preparedness Committees.

The outgrowth of this meeting has been already felt. "We talked about the conservation of balance throughout the counties of the State, feeling that if we could maintain a favorable balance geographically and in regard to the types and activities of the doctors, that would forestall resettlement, as it were, of many physicians." (This quotation is from a report to the Council.)

At the present time there is a movement under way through certain extramedical committees and services, and among the foreign physicians themselves, to settle into these communities where doctors have left for the armed service, and the Committee feels that we might be able through that method (con-

servation of balance) to aid in the care of the public health.

The Procurement and Assignment Service says (December 7, 1942) that upstate New York at the present time has oversubscribed its full quota and that from now until spring at least, and perhaps all of 1943, most physicians processed will be recruited from the metropolitan area.

Through the efforts of Dr. Louis H. Bauer, Chairman of the Medical Preparedness Committee of the New York State Medical Society, and Dr. Joseph R. Clemmons, State Chairman of Procurement and Assignment, meetings are being held in most sections of the State at the present time with the chairmen of Medical Preparedness Committees of all county societies.

On the question of balance, Dr. Clemmons said:

"Do not declare available any man if you consider him essential to the health and welfare of your community. If you declare a man essential, it is your duty to convince him that he is. He should be instructed not to make application for commission either at the Recruiting Board or to the Surgeon General's Office without first consulting the local Medical Preparedness Committee.

"It is the responsibility of the Medical Preparedness Committees to evaluate their men and accordingly maintain a numerical balance in so far as is possible."

Local Needs for Physicians, Civil and Industrial

As of December 5, 1942, our President has placed all matters of Manpower, both civil and military, under the control of Chairman Paul V. McNutt, of the Federal Security Board. What this may mean in the matter of the movement of physicians has not yet been made clear. However, the present need for physicians in civil and industrial life is slight. This question should be followed actively by the Public Relations Committees of the State and the counties. Any communities found short would promptly receive the assistance of these committees. There are many regularly licensed physicians in New York State who are willing to change their place of residence to supply (or fill) any medical needs in civil or industrial communities.*

* The Committee is indebted to the A.M.A. for Chart 1, for figures used in the tables, and for other material which appeared in the J.A.M.A. of May 9, 1942.

TUBERCULOSIS INVOLVING THE GENITOURINARY TRACT FOLLOWING TRAUMA

J. C. McCLELLAND, M. D., Toronto, Canada

TRAUMA as a cause of tuberculosis in the genitourinary tract is extremely rare. In the preparation of this paper, it was necessary to look far afield from my local sphere of urologic experience in Toronto, in order to collect a few cases. A letter was sent to the Workmen's Compensation Boards in every province of the Dominion of Canada, and from a large number of claims the Medical Directors of the Provinces of Manitoba, Quebec, and Nova Scotia very kindly forwarded me their cases, which I am presenting to you today. No claims had occurred in the other provinces. A few cases were collected from the Weston Sanatorium just outside of Toronto, one from Dr. Slotkin in Buffalo, and one from the Toronto General Hospital, which had been reviewed by the Workmen's Compensation Board of Ontario.

Incidence

One may get an idea as to the rarity of these cases by the figures of the Medical Director of the Manitoba Workmen's Compensation Board, Dr. A. J. Fraser, when he says, "the number of claims resulting from accidents during the past twenty-five years of operation of the Board now amounts to approximately 227,730," from which he had two cases of tuberculosis of the genitourinary tract, which are quoted below. The percentage of incidence becomes 0.00087 of 1 per cent, or approximately $\frac{9}{10,000}$ of 1 per cent, of accidents.

Case Reports

The following cases are divided into seven groups, according to the structures involved in the tuberculous process:

I. Renal.....	1 case
II. Renal and genital.....	4 cases
III. Bone and renal.....	1 case
IV. Joint and genital.....	1 case
V. Pulmonary and genital....	1 case
VI. Genital only.....	4 cases
VII. Genital before trauma.....	5 cases
Total 17 cases	

In the case histories presented below the

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1942.

pathologic reports are quoted where possible. The histories are necessarily quite short.

I. RENAL

Case 1 (P. P., Aged 27—Claim No. 108351 Quebec)

History.—On September 21, 1932, he fell from a height of 8 feet striking his back against a rock. Passed blood in the urine the day of the accident. Examination on November 7 and November 12 showed a left renal tuberculosis and a sound right kidney. A left nephrectomy was performed on November 18, 1932. Discharged from hospital December 21, 1932.

Decision.—The Commission decided that the claimant was afflicted with tuberculosis of the left kidney prior to his accident, but allowed the claim as one of aggravation. They paid compensation to May 20, 1933, (eight months) together with the hospital bill and the surgeon's fee, but did not allow any permanent disability connected with the trauma.

Comment.—Renal tuberculosis was present previous to the accident which aggravated the condition and led to the immediate removal of the kidney.

II. RENAL AND GENITAL

Case 2 (E. B., Aged 52—Claim No. 406432 Quebec)

History.—On March 21, 1934, this man sustained an injury to the left testicle which was later diagnosed as tuberculous epididymitis with involvement of the testicle. A left castration was performed August 25, 1934, five months later. Subsequently, he was found to have a left renal tuberculosis.

Decision.—The Commission paid compensation up to October 3, 1934 (seven months) and allowed a 5 per cent permanent disability, but denied all liability as to the renal tuberculosis, as it concluded that the man had an established renal tuberculosis at the time of the accident. The claim was allowed merely on an epididymitis and orchitis, as being an aggravation of a tuberculosis already present.

Comment.—An epididymitis developed here after trauma in the presence of renal tuberculosis.

Case 3 (P. K., Aged 32—Claim No. 122061 Manitoba)

History.—On September 16, 1932, while helping to lift a loaded hand car, he is alleged to have strained himself and to have been seized with a pain in the groin. He ceased work half a day

later and was admitted to hospital. His surgeon reported a traumatic orchitis, as the swelling suggested a hematoma. On November 29, two months later, a left orchidectomy was done and the pathologic report showed tuberculous epididymitis and orchitis.

Four months later, on January 23, 1933, a tuberculous epididymitis developed in the right side, which progressed to form an abscess.

Cystoscopic investigation revealed a bilateral renal tuberculosis.

Complete chest examination was negative for any evidence of tuberculosis.

Decision.—The Board accepted liability until the healing of the wound in the left side.

Comment.—In the presence of bilateral renal tuberculosis a sudden muscular strain is alleged to have produced a sudden pain in the left groin, which was found subsequently to be a tuberculous epididymitis. Later the second epididymis became involved. Two months elapsed between the accident and the orchidectomy.

Case 4 (H. K., Aged 51—Claim No. 155815 Manitoba)

History.—On August 1, 1936, he fell while at work and received a direct injury over the genitalia. He remained at work for a day and a half and sought medical advice two days following the accident. The left testicle was swollen to twice the normal size and was very painful. Nineteen days after the accident, the painful swelling had subsided but the epididymis was still hard. Six weeks after the accident an abscess had formed and a left epididymectomy was performed, because the condition was considered tuberculous.

The pathologic report was tuberculous epididymitis. The attending surgeon commented: "apparently a more or less quiescent process lighted up by injury." The patient had a discharging sinus for months.

On June 22, 1937, or eleven months after the accident, he was admitted to the Winnipeg General Hospital for cystoscopy and a diagnosis of bilateral renal tuberculosis was made.

His chest examination was negative for tuberculosis, as was his radiologic examination.

He was allowed compensation until the healing of his operation wound.

Comment.—It was considered that the patient had an injury which became tuberculous in the presence of renal tuberculosis.

Case 5 (J. W. N., Aged 29—W. C. B. Nova Scotia)

History.—On July 16, 1936, the patient was struck on the left testicle with the end of a crowbar. Pain, swelling, and hematuria followed. There was no previous history of hematuria. The swelling remained. An incision was done three weeks after the accident, and pus was evacuated from an abscess of the epididymis. Frequency developed, the abscess failed to heal, and on January 25, 1937, six months after the accident,

he was admitted to hospital. The left epididymis, vas, and both seminal vesicles were thickened, the urine was positive for tubercle bacilli, and there was a left apical tuberculosis. The dorsal and lumbar spines were negative for evidence of tuberculous disease.

Sanatorium treatment was started and a cystoscopic examination was not attempted for fear of starting meningitis. The frequency continued to grow worse.

He was readmitted to hospital on August 2, 1937, and cystoscopy showed a bilateral renal tuberculosis. He continued under treatment until August 23, 1940, when the Board considered that he had recovered from the effects of the accident of July 16, 1936. At that time there was a questionable activity in his lungs, but he returned to work. The Medical Officer of the Board says: "As this case developed it became more and more apparent that the pre-existing focus of infection in the lungs was present and active, in all probability before the accident in 1936."

Comment.—This patient was one of those unfortunate individuals who harbor an organism over which they cannot gain control, but it progresses from place to place. The lowered vitality of the injured area allowed the tubercle bacilli to gain a foothold and produce a lesion. It is likely that the renal and pulmonary lesions were present at the time of the injury and that the tuberculous epididymitis developed secondary to them.

III. BONE AND RENAL

Case 6 (S. P., Aged 21—Dr. George Slotkin's Case, Buffalo)

History.—The patient was first seen on November 22, 1932, complaining of frequency, urgency, and dysuria associated with pain in the left costo-muscular angle. A left renal tuberculosis was diagnosed and this kidney removed. The right one showed no evidence of any lesion.

Her previous history was that fourteen months before presenting herself to Dr. Slotkin her right wrist had been lacerated in a car accident. This healed at first but broke down in a month and a tuberculous semilunar bone was removed.

Her chest had showed no evidence of tuberculosis and there was no other illness suggesting a possible focus for the original trouble in the right semilunar bone.

Comment.—This case showed a renal tuberculosis diagnosed fourteen months following the accident to the wrist. Dr. Slotkin's final note says: "This case was of special interest from the medicolegal point of view because of the correlation of events from the time of the injury to her nephrectomy. Originally, the attorney sued for the injury of the hand only, but the bill of particulars was amended to include the kidney infection. At the litigation the relationship of the kidney infection to the injury was established on

the basis of: (a) urinary tuberculosis being a secondary disease dependent on a primary focus, in the case of the injured wrist; (b) the element of time between the appearance of the renal tuberculosis and the tuberculous wrist."

The kidney which was removed had rather an advanced area of destruction which had probably originated from the bone lesion in the wrist. It has also been shown by Dr. Davis and myself in our series of bone tuberculosis that 22.9 per cent developed renal tuberculosis.*

In the Orthopedic Service for tuberculosis at the Weston Sanatorium, I am informed that from 15 to 20 per cent of the patients admitted attribute their bone lesion to some injury. Invariably, investigation has showed that the tuberculous process must have been present before the injury, since it was too well established to be due to a recent injury.

IV. JOINT AND GENITAL

Case 7 (A. O. V., Aged 37)

History.—The patient was admitted to Weston Sanatorium on June 16, 1941, for treatment of a tuberculous knee, which first gave symptoms in 1934. He was in an accident in 1934, in which he was crushed in a mine and the left testicle became swollen and painful. He was treated for venereal disease first and later saw another doctor, who in May, 1934, removed a tuberculous testicle and epididymis. Several weeks later an abscess developed in the scar, tuberculous pus was obtained, and the sinus took two and a half years to heal.

The right epididymis is not involved and the urine has been negative for pus cells and tubercle bacilli on several examinations by smear and culture.

This patient applied for compensation but it was not allowed. He is now under treatment for his knee condition.

Comment.—This was a case of tuberculosis epididymitis following trauma, which occurred at the same time as an arthritis in the patient's knee, and which has subsequently shown itself to be tuberculosis.

V. PULMONARY AND GENITAL

Case 8 (G. S., Aged 54, Weston Sanatorium)

History.—This patient had an active pulmonary tuberculosis. He had a bilateral scrotal swelling which was partly due to epididymitis and partly due to bilateral hydroceles. These swellings had followed the use of a truss for bilateral inguinal herniae, having come on about three months after it was used first. There was no frequency, but the bladder urine contained pus cells and guinea pigs inoculated with it were positive for tubercle bacilli. His death was caused by his pulmonary disease.

Autopsy showed bilateral tuberculosis in both epididymes, while both kidneys were negative

for evidence of tuberculosis, both in the gross and on section.

Comment.—This was a case of injury to the epididymes by a truss, which caused tuberculosis in a patient who had an active pulmonary tuberculosis.

VI. GENITAL

Case 9 (H. E. S., Aged 25)

This young man was admitted to Toronto General Hospital on September 19, 1924, and discharged on November 4, 1924.

History.—On August 12, 1924, one month before admission, he was injured in the left testicle while carrying a piece of timber. There was a good deal of pain that night and the next day, though he went to his work. Later in the day he had to stop because he could walk only with great difficulty. He stayed in bed three weeks before the swelling started to subside, but some still remained and he was admitted to hospital.

Examination showed the left cord to be the size of one's little finger, with swelling in the whole epididymis and a fluctuant mass the size of a 25-cent piece involving the skin. The left seminal vesical was indurated and enlarged. The chest entirely negative. Blood pressure was 152/72.

Urinalysis.—The urine was alkaline; specific gravity, 1.030; no albumin; no sugar. Microscopic examination revealed occasional pus cell and tubercle bacilli, found on guinea pig inoculation.

Nonprotein nitrogen was 26 mg. Wassermann was negative.

Operation.—Left orchidectomy and epididymectomy, with removal of cord.

Pathologic Report.—Tuberculous epididymitis and orchitis.

Comment.—No other tuberculous focus was found. The tubercle bacilli in the urine might have come from a renal tuberculosis, the tuberculous epididymitis, or both. Ureteral catheterization was not done.

Case 10 (L. D., Aged 27—Claim No. 409070 Quebec)

History.—On May 5, 1934, there was an injury to the left testicle, which was followed by a swelling in the epididymis and the formation of an abscess. This was opened on July 5, just two months after the accident.

Decision.—The Commission was of the opinion that the claimant was affected with tuberculosis, allowed the claim as being an aggravation of a pre-existing pathologic condition, without permanent disability, and paid compensation up to August 28, 1934 (three and a half months).

Case 11 (E. B., Aged 43—Claim No. 482454 Quebec)

History.—On November 13, 1935, the patient fell against a stump, striking his right groin. He later developed a bilateral tuberculous epididymitis.

*J. Urol. 47:No. 3 (March) 1942.

later and was admitted to hospital. His surgeon reported a traumatic orchitis, as the swelling suggested a hematoma. On November 29, two months later, a left orchidectomy was done and the pathologic report showed tuberculous epididymitis and orchitis.

Four months later, on January 23, 1933, a tuberculous epididymitis developed in the right side, which progressed to form an abscess.

Cystoscopic investigation revealed a bilateral renal tuberculosis.

Complete chest examination was negative for any evidence of tuberculosis.

Decision.—The Board accepted liability until the healing of the wound in the left side.

Comment.—In the presence of bilateral renal tuberculosis a sudden muscular strain is alleged to have produced a sudden pain in the left groin, which was found subsequently to be a tuberculous epididymitis. Later the second epididymis became involved. Two months elapsed between the accident and the orchidectomy.

Case 4 (H. K., Aged 51—Claim No. 155815 Manitoba)

History.—On August 1, 1936, he fell while at work and received a direct injury over the genitalia. He remained at work for a day and a half and sought medical advice two days following the accident. The left testicle was swollen to twice the normal size and was very painful. Nineteen days after the accident, the painful swelling had subsided but the epididymis was still hard. Six weeks after the accident an abscess had formed and a left epididymectomy was performed, because the condition was considered tuberculous.

The pathologic report was tuberculous epididymitis. The attending surgeon commented: "apparently a more or less quiescent process lighted up by injury." The patient had a discharging sinus for months.

On June 22, 1937, or eleven months after the accident, he was admitted to the Winnipeg General Hospital for cystoscopy and a diagnosis of bilateral renal tuberculosis was made.

His chest examination was negative for tuberculosis, as was his radiologic examination.

He was allowed compensation until the healing of his operation wound.

Comment.—It was considered that the patient had an injury which became tuberculous in the presence of renal tuberculosis.

Case 5 (J. W. N., Aged 29—W. C. B. Nova Scotia)

History.—On July 16, 1936, the patient was struck on the left testicle with the end of a crowbar. Pain, swelling, and hematuria followed. There was no previous history of hematuria. The swelling remained. An incision was done three weeks after the accident, and pus was evacuated from an abscess of the epididymis. Frequency developed, the abscess failed to heal, and on January 25, 1937, six months after the accident,

he was admitted to hospital. The left epididymis, vas, and both seminal vesicles were thickened, the urine was positive for tubercle bacilli, and there was a left apical tuberculosis. The dorsal and lumbar spines were negative for evidence of tuberculous disease.

Sanatorium treatment was started and a cystoscopic examination was not attempted for fear of starting meningitis. The frequency continued to grow worse.

He was readmitted to hospital on August 2, 1937, and cystoscopy showed a bilateral renal tuberculosis. He continued under treatment until August 23, 1940, when the Board considered that he had recovered from the effects of the accident of July 16, 1936. At that time there was a questionable activity in his lungs, but he returned to work. The Medical Officer of the Board says: "As this case developed it became more and more apparent that the pre-existing focus of infection in the lungs was present and active, in all probability before the accident in 1936."

Comment.—This patient was one of those unfortunate individuals who harbor an organism over which they cannot gain control, but it progresses from place to place. The lowered vitality of the injured area allowed the tubercle bacilli to gain a foothold and produce a lesion. It is likely that the renal and pulmonary lesions were present at the time of the injury and that the tuberculous epididymitis developed secondary to them.

III. BONE AND RENAL

Case 6 (S. P., Aged 21—Dr. George Slotkin's Case, Buffalo)

History.—The patient was first seen on November 22, 1932, complaining of frequency, urgency, and dysuria associated with pain in the left costo-muscular angle. A left renal tuberculosis was diagnosed and this kidney removed. The right one showed no evidence of any lesion.

Her previous history was that fourteen months before presenting herself to Dr. Slotkin her right wrist had been lacerated in a car accident. This healed at first but broke down in a month and a tuberculous semilunar bone was removed.

Her chest had showed no evidence of tuberculosis and there was no other illness suggesting a possible focus for the original trouble in the right semilunar bone.

Comment.—This case showed a renal tuberculosis diagnosed fourteen months following the accident to the wrist. Dr. Slotkin's final note says: "This case was of special interest from the medicolegal point of view because of the correlation of events from the time of the injury to her nephrectomy. Originally, the attorney sued for the injury of the hand only, but the bill of particulars was amended to include the kidney infection. At the litigation the relationship of the kidney infection to the injury was established on

charging sinus makes one suspect tuberculosis.

Also, a swelling in the epididymis which

comes on later than one to three months following the accident must not be considered to be due to the injury.*

* In conclusion, I want to thank those who have so kindly allowed me to quote their cases, particularly the medical directors of the various Workmen's Compensation Boards—viz.: Dr. A. J. Fraser, of Manitoba; Dr. Arthur LeClerc, of Quebec; Dr. D. E. Bell, of Ontario;

and Dr. H. L. Scammell, of Nova Scotia. I also wish to thank Dr. G. E. Slotkin, of Buffalo, for allowing me to quote his case, and Dr. K. E. Davis, of Weston Sanatorium, for his kindness in helping in the collection of some of the above material.

FAMILY HELP

The sharp increase in the number of quack psychologists and self-styled "family problem experts" in recent years reflects the strain of modern industrial life. Wartime conditions have heightened pre-existing tensions and placed added strain on the stability of the family unit.

To meet the growing need and desire for help with personal problems, the Jewish Social Service Association in New York City has established a Consultation Center for the middle-income group.

This new service applies the principles of modern family case work—heretofore utilized chiefly in behalf of welfare clients—to people of moderate means with personal or family problems with which they cannot cope. It does not

provide medical or legal advice but recommends recourse to either, if necessary, and stands ready to assist the doctor or lawyer when nonprofessional obstacles impede the realization of his professional aims for a patient or client.

The Consultation Center is operated on a nonprofit basis, though all applicants are required to pay a small fee, with a minimum charge of one dollar per appointment. The five regular district offices of the Association will continue to serve those unable to pay even a nominal amount for counsel and help.

Relief from anxiety is a recognized therapeutic agent. When a patient's family worries interfere with successful treatment or rehabilitation, this new Consultation Service may give the physician useful assistance.—*J. of the Med. S. County N.Y.*

Decision.—The Commission allowed the claim as being an aggravation of a pre-existing pathologic condition and paid compensation for total temporary incapacity to December 16, 1935, inclusively. They decided there was no permanent disability connected with the accident.

Case 12 (A. R., Aged 41—Claim No. 795727 Quebec)

History.—On November 18, 1940, following a trauma, A. R. displayed a tuberculous epididymitis and orchitis on the left side. Later on, the tuberculosis involved the right epididymis. A bilateral castration was done.

Decision.—The Commission allowed the claim as an aggravation of a pre-existing pathologic condition in the case of the left side, but denied all liability in connection with the right side. No permanent disability was allowed.

VII. GENITAL BEFORE TRAUMA

Case 13 (G. D., Aged 45—Claim No. 487842 Quebec)

History.—On December 27, 1935, the patient sustained an injury to the left testicle. Examination showed the presence of a tuberculous epididymitis, which existed *before* the trauma.

Decision.—The Commission accepted the claim as an aggravation and paid compensation up to February 4, 1935.

Case 14 (A. P., Aged 33—Claim No. 516325 Quebec)

History.—On June 19, 1935, this man sustained an injury to the right testicle. Previously, he had had a left castration for a tuberculous epididymitis. A right epididymectomy was done.

Decision.—The Commission allowed the claim as an aggravation of a right epididymal orchitis which was tuberculous and which existed prior to the accident. No permanent disability was allowed as a result of the trauma.

Case 15 (H. McA., Aged 37—Claim No. 518950 Quebec)

History.—On July 7, 1936, this patient's feet slipped and he fell; he felt a pain in the right testicle. Immediate examination revealed that he was suffering from a tuberculous epididymitis previous to his accident. On August 27, 1936, right castration was carried out.

Decision.—The Commission allowed this claim as being an aggravation of a pre-existing pathologic condition. Compensation was paid to September 30, 1936, and no permanent disability was allowed.

Case 16 (L. A., Aged 32—Claim No. 519990 Quebec)

History.—On June 9, 1936, the claimant fell straddling over the gable of a house, severely injuring his scrotum. Immediately after examination an epididymal and fistulous tuberculosis of the left side was diagnosed. It was a condition

that existed before the accident and aggravated by trauma.

Decision.—The Commission decided to pay compensation up to September 18, 1936, but did not allow any permanent disability.

Case 17 (C. X., Aged 29—Claim No. 533282 Quebec)

History.—On July 30, 1937, he sustained an injury to the right testicle. A chronic nodular tuberculous epididymis was diagnosed. This was not aggravated by the trauma.

Decision.—No aggravation of the pre-existing condition occurred and the claim was dismissed.

Summary

In this group of patients one sees tuberculosis in the genitourinary tract which has come to an area where no tuberculosis had existed previously. The lowered resistance and injury to that area produced a bed where tubercle bacilli in circulation found a good culture medium and produced a lesion. As these cases have illustrated, they have come from foci in the lungs, bones, and joints, and are secondary to other foci in the urinary tract. Genital tuberculosis had developed in the presence of renal tuberculosis. Genital tuberculosis spread from the injured testicle to the uninjured one.

This series includes five cases in which the genital tuberculosis was present in the organ which was injured. Once established in the genitourinary tract, the tuberculosis advances in the usual well-recognized ways. One should bear in mind that a high percentage of all nontraumatic cases of genital tuberculosis accompany or follow renal tuberculosis and the possibility of its presence should lead to routine cystoscopic investigation of the kidneys. This examination should not be omitted and the time for carrying it out should be when the acute symptoms in the epididymis have subsided.

A tuberculous lesion in the genitourinary tract is always secondary to some other focus. Even in trauma this must hold true, and is true in most of the cases quoted above. Where the original focus is not found, we presume that it must have been present and was probably healed. The injury to the part merely sets up a favorable site for the organisms to thrive in and form a pathologic lesion.

In the acute stage, a diagnosis cannot be made, but if after a period of three weeks or more the swelling does not subside, one should suspect tuberculosis. In addition, the formation of an abscess or, better, a chronic dis-

FIG. 1. Aspiration biopsy of spherical mass in left lung, using biplane fluoroscopic guidance. Roentgenograms A and B show point of needle in center of "tumor" after it was directed there under biplane fluoroscopic control. A tentative diagnosis of a dermoid cyst based on gross appearance of aspirated fluid was verified by histologic examination. Roentgenogram A was exposed by horizontal fluoroscopic beam with patient lying on right side, while vertical beam was used for B. Arrow indicates fluid level seen after injection of air.

genography, the radiologist was sometimes unable to offer an opinion concerning disease in the lung because of these interfering shadows. By means of the body section technic these shadows are eliminated, and recognition of the process is often possible (Fig. 3).

Experience with planigraphy over a period of several years indicates that it should be employed in every chest problem not solved by conventional roentgen methods. Our results are more spectacular with lung tumors and tuberculous cavities than with other abnormalities, but its use is by no means restricted to the demonstration of these conditions. Not only is a tumor identified by planigraphic separation of its shadows from those caused by surrounding dense lung, but also the determination of its depth allows accurate localization for aspiration biopsy (Fig. 3).

Providing that the tumor arises in one of the major bronchial divisions, the resultant narrowing or occlusion of the bronchus is demonstrable even though the tumor itself may be better visualized on a roentgenogram exposed at a slightly different depth than the

one that shows the deformed bronchus. Such a finding points to the existence of the major portion of the growth outside the bronchial lumen.

Constriction and invasion of the lateral tracheal walls that result from conditions such as Hodgkin's disease and adenoma and carcinoma of the thyroid are clearly demonstrated by antero-posterior planigraphy, and this procedure is the most satisfactory way to show side-to-side narrowing of the trachea, since the spine and mediastinal structures interfere when visualization is attempted through the use of conventional roentgen ray methods (Fig. 2).

Foreign bodies of poor opacity, demonstrable only by postero-anterior or antero-posterior roentgenograms but not by lateral projections (because of adjacent or surrounding atelectatic lung), are accurately localized by antero-posterior planigraphy. This localization is possible because the antero-posterior depth of the planigraphic section showing the foreign body is recorded on the film, and thus its position in the lung and its relationship to a nearby bronchus are apparent.⁴

RECENT ADVANCES IN ROENTGEN DIAGNOSIS OF DISEASES OF THE CHEST INCLUDING BODY SECTION ROENTGENOGRAPHY (PLANIGRAPHY)

BARTON R. YOUNG, M.D., Philadelphia

THE roentgen diagnosis of diseases of the chest remains difficult despite continued improvement in technic and newer methods of examination. For this reason it is necessary that the radiologist obtain as much information as possible about the chest by a combination of fluoroscopy and roentgenography before interpreting the results in the light of the history and clinical findings.

Fluoroscopy is an indispensable preliminary procedure not only because it yields invaluable information concerning the movements of the heart, lungs, and diaphragm, but also because it makes possible an intelligent film examination by revealing the location and nature of the disease.

Frequently fluoroscopy is more informative than any other single roentgen procedure. For example, when a nonopaque foreign body is lodged in the bronchial tree, its presence and position are detected by observing abnormal filling and emptying of the lung distal to the occlusion, with a characteristic shift of the heart and mediastinal structures during inspiration and expiration.

Fluoroscopic evaluation of the excursion of the leaves of the diaphragm is an essential part of the diagnostic procedure for a nonopaque foreign body, and it is equally important in the diagnosis of bronchial tumor, subdiaphragmatic infection or abscess, phrenic nerve paralysis, and emphysema because in all these conditions the diaphragm is either unilaterally or bilaterally limited in motion, depending upon the nature and location of the disease.

A discussion of fluoroscopy is not complete without mention of the value of biplane fluoroscopic guidance to the bronchoscopist during removal of an opaque foreign body, and to the thoracic surgeon while performing aspiration biopsy. Success in removing foreign bodies that are visualized with difficulty and also in obtaining satisfactory biopsy tissue for histologic study is largely due to adequate fluoroscopic guidance made possible

by the use of well-engineered equipment such as the biplane fluoroscope devised by Chamberlain.¹ Using this type of fluoroscope or a model equally efficient, an experienced radiologist is able to guide accurately the surgeon's aspirating needle into a dense tumor or cyst located anywhere in the chest (Fig. 1). In dealing with otherwise inaccessible lesions, aspiration biopsy frequently results in a positive diagnosis when all other methods, short of surgical exploration, are unsuccessful.²

After completion of the fluoroscopic study, roentgenograms of the chests are exposed with the patient in positions that best demonstrate the disease. The number of roentgenograms that are exposed, in addition to the conventional postero-anterior film, varies according to the diagnostic needs. Lesions of sufficient density to cast well-defined shadows are usually best localized and depicted by ventral (postero-anterior view) and lateral projections. When the disease process is very dense, an antero-posterior projection, using moderate overexposure and the Potter-Bucky diaphragm, is a worth-while addition to the routine film studies (Fig. 2B). Stereoscopic and oblique projections are frequently very informative and are included when indicated.

Lipiodol bronchography is an essential procedure in the diagnosis of bronchiectasis and is extremely valuable in revealing the site and extent of a stenosis or occlusion of the bronchial tree due to tumor or a non-neoplastic process. Farinas³ reports better results with solutions of organic salts of iodine such as uroselectan than with lipiodol in the bronchographic study of bronchiogenic carcinoma, especially when there is a high degree of obstruction of the bronchial lumen. These watery solutions flow more readily and are absorbed more rapidly than iodized oils, but better contrast is obtained with the latter.

Frequently the diagnosis of a disease process in the lung remains obscure despite detailed fluoroscopic and film studies because of the absence of a characteristic roentgen appearance of the disease or the failure of visualization on account of confusing superimposed shadows produced by the rib cage, spine, a layer of pleural fluid, or adjacent atelectatic lung. Until the advent of body section roent-

From the Department of Radiology, Temple University Medical School and Hospital, Philadelphia.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, April 30, 1942.

FIG. 4. Tuberculous cavity demonstrated by planigraphic roentgenogram B, not revealed by conventional postero-anterior view, A, or Potter-Bucky diaphragm studies. Annular or ovoid planigraphic shadows must be evaluated cautiously as emphysematous blebs or bullae occasionally simulate tuberculous cavities.

Summary

It is the primary duty of the radiologist to obtain the maximum amount of visual evidence of a disease process in the chest by employing every roentgen procedure that is an aid in diagnosis. The value of careful preliminary fluoroscopy is emphasized because this very important part of the diagnostic procedure is too frequently omitted. Biplane fluoroscopy, performed with well-engineered equipment, is invaluable to the endoscopist and thoracic surgeon when they need visual guidance for special procedures, such as aspiration biopsy and bronchoscopic removal of deeply lodged foreign bodies of poor opacity.

Body section roentgenography gives visual information not obtained by any other type of roentgen examination, especially when superimposed shadows prevent the demonstration of the disease by conventional methods. The method is particularly valuable for the demonstration of lung cavities and tumors not visualized by ordinary roentgen studies. If the examination is done thoroughly, planigraphy is as reliable in ruling out cavitation or

tumor of any appreciable size as it is in establishing the presence of either of these two conditions.

Tracheal stenosis, or distortion of the tracheo-bronchial tree resulting from any cause, is made apparent even in the presence of dense neighborhood structures, and, when indicated, planigraphy aids in localization of foreign bodies in the lungs.

The value of the test of irradiation to differentiate a lymphoblastoma from other chest tumors is briefly discussed.

The numerous ways in which roentgen rays are utilized for the recognition of diseases of the chest are indicated in this paper, but, despite their diagnostic value, the rays are used with maximum effectiveness only when there is close cooperation between clinician and radiologist and the roentgen results are carefully correlated with the clinical findings.

FIG. 2. Comparison of conventional and planigraphic roentgenograms of tracheal stenosis due to intrathoracic extension of diffuse adenomatous goiter. A—Conventional postero-anterior film affords poor visualization of trachea despite deliberate overexposure. B—Potter-Bucky antero-posterior film reveals goiter and tracheal narrowing, but deformity of trachea is demonstrated much better by planigraphic roentgenogram, C.

Planigraphy is invaluable for the demonstration of tuberculous and nontuberculous cavities not revealed by conventional roentgen studies because of interfering shadows, such as those caused by adjacent bony structures, thickened pleura, or surrounding dense lung (Fig. 4). For this reason the method is considered indispensable for patients with thoracoplasty when the clinical and laboratory evidence indicates breakdown of lung tissue and the conventional roentgen studies are negative for cavitation. Many times previously undetected tuberculous cavities are rendered visible by planigraphy when the disease is apparently controlled either by collapse therapy or by conservative treatment. Negative plani-

graphic findings are reliable for ruling out the cavity, providing that the examination is done thoroughly and that closely spaced, thin sections of the lung are obtained.

One additional diagnostic aid that is occasionally useful is the test of irradiation. This therapeutic test is carried out when lymphoblastoma is suspected and when there are no accessible lymph nodes for biopsy. A dose of 100 r, or even less, to the front and back of the lesion twice a week for two weeks is usually ample to produce a prompt decrease in the size of a neoplasm belonging to this group although this amount of irradiation will not appreciably affect other tumors in the chest.

FIG. 3. Planigraphic demonstration and localization of primary bronchial carcinoma. Rib and clavicle shadows interfere with visualization of tumor in A and B. Successful aspiration biopsy carried out despite poor definition of shadow on biplane fluoroscopic screen because planigram C localized lesion as to depth.

1921 through 1935, inclusive; and the annual number of deaths for each year from 1936 through 1941, for disease titles in which consistent reductions in mortality occurred. In all fourteen diseases, the numbers of deaths in 1937 and 1938 were fewer than the previous five-year average, and remained so thereafter. In fact, the numbers of deaths for all except one of the diseases (appendicitis) were less in 1937 or 1938 than the lowest number in any year from 1921 through 1935. The more striking changes occurred early in the period. For example, marked reductions were seen in scarlet fever and erysipelas mortality in 1937, and marked changes were seen in the mortality from diseases of the ear and mastoid and diseases of the pharynx and tonsils in 1938. In other conditions marked reductions occurred later, as in meningitis not due to the meningococcus, and pneumonia (all forms), for which sulfapyridine, sulfathiazole, and sulfadiazine were introduced in 1939, and afterward; and in appendicitis, for which combined local and general sulfonamide treatment for complicating peritonitis became widespread only in 1940, and afterward. The unusual reductions in mortality were superimposed on a previous downward trend in scarlet fever, measles, and infections during childbirth and puerperium. In meningococcus meningitis and in measles marked irregular variations associated with epidemic prevalence occurred before the introduction of the sulfonamide drugs. Examination of Table 2 shows that the changes in mortality for all fourteen titles in 1937, and following years, were either greater or more persistent or both greater and more persistent than any changes that occurred between 1921 and 1936, before the introduction of the sulfonamide drugs.

TABLE 1.—AMOUNTS OF SULFONAMIDE DRUGS PURCHASED ANNUALLY FOR USE IN NEW YORK CITY MUNICIPAL INSTITUTIONS*

Drugs	1937	1938	1939	1940	1941
		<i>(Amounts in Kilograms)</i>

Sulfathiazole				8	613
Sulfadiazine					115
Total	260	545	884	1,201	1,216

* Courtesy of the New York City Department of Purchase.

The relative amount of change in mortality rates per 100,000 population following the introduction of the sulfonamide drugs is shown in Table 3, in which the average annual mortality for the five-year period 1932 through 1936, before the introduction of the sulfonamide drugs, is compared with the average annual mortality for the five-year period 1937 through 1941. The diseases are arranged in the order of the percentage reductions in mortality, which range from 82 per cent for erysipelas to 29 per cent for appendicitis. In the case of measles, scarlet fever, abortion with mention of infection, and infection during childbirth and puerperium, different bases are commonly used for calculation of the mortality rates—namely, population less than 5 years of age, population less than 15 years of age, and the annual number of live births. If these mortality rates were calculated in this manner, however, there would be little change in the percentage reductions in mortality following 1937.

The mortality for 1941, the latest year for which figures are available, is also given in Table 3, to show the present mortality from these conditions at the end of five years of progressive reductions. It is estimated that if the average mortality rate of 137.5 deaths per 100,000 population during the five years

MORTALITY FROM DISEASES TREATED WITH THE SULFONAMIDE DRUGS

WHEELAN D. SUTLIFF, M.D., New York City

NUMEROUS reports of favorable therapeutic effects from the administration of the sulfonamide drugs in appropriate diseases have led to the expectation that striking reductions in mortality rates from many bacterial infections will follow the widespread use of sulfonamide therapy. Data as to the amount of the sulfonamide drugs used and the mortality* from fourteen different diseases in New York City were therefore tabulated to show the changes since the introduction of the various sulfonamide drugs.

Each sulfonamide drug was widely used soon after it became generally available. Records of the annual purchases (see Table 1) by the New York City Municipal Purchase Department, for use in city hospitals and clinics, show that considerable quantities of sulfanilamide were first purchased in 1937. Its use increased in 1938. In 1939, the use of sulfanilamide continued to increase, and sulfapyridine was also purchased. In 1940, the use of sulfanilamide was stationary and the use of sulfapyridine increased. Sulfathiazole was purchased in small amounts. In 1941, sulfathiazole was the principal drug purchased. The use of sulfanilamide and sulfapyridine declined; and sulfadiazine was also used, but in small amounts. Less complete data from pharmacies and voluntary hospitals confirm the relative popularity of the different drugs. Data from these sources indicate, however, that for about one year before the general use of each new drug relatively small amounts were supplied for study, without charge, by pharmaceutical companies to certain institutions and physicians. It is believed that only the wide general use, such as is indicated by the figures for municipal institutions, is of significance in connection with marked changes in mortality rates.

The following fourteen diseases were selected for tabulation because deaths ascribed to them are commonly associated with infections by micro-organisms susceptible to

the sulfonamide drugs, and because marked reductions in the mortality from each disease occurred during the period following the introduction of the sulfonamide drugs: cerebrospinal (meningococcus) meningitis; scarlet fever; erysipelas; measles; meningitis (not meningococcus); diseases of the ear and mastoid process; pneumonia (all forms); empyema; diseases of the pharynx and tonsils; appendicitis; abortion with mention of infection; infection during childbirth and puerperium; phlegmon and acute abscess; osteomyelitis and periostitis.

The deaths are classified according to the *International List of Causes of Death*, which is in use throughout the Registration Area of the United States, and are therefore comparable to those reported elsewhere. Only the primary cause of death is considered in this study, since no marked changes were made during the period in the application of the procedures described in the *Joint Cause Manual*, which describes the choice of primary and secondary and contributory causes of death from two or more reported causes. Revisions of the *International List of Causes of Death*, which became effective in 1931 and 1940, required readjustment in the annual reported deaths in only two titles, in 1940 and 1941—namely, abortion with infection and infection during childbirth and puerperium. In four titles, changes were made that could not be adjusted, and deaths for some of the earlier years were omitted. It is not possible to separate all reported deaths from infections susceptible to the action of the sulfonamide drugs from all other causes of death in these data, because the essential bacteriologic information was not regularly obtained by physicians, and was not required by the *International List of Causes of Death*. Many other disease titles contain some deaths ascribed to infections considered susceptible to the action of the sulfonamide drugs, but they are not tabulated here unless consistent changes in the annual number of deaths were noted following the introduction of the sulfonamide drugs.

Table 2[†] shows the average annual numbers of deaths for three five-year periods, from

* Assistant Director, Bureau of Laboratories, New York City Department of Health.

† Data on mortality were supplied through the courtesy of Mr. Thomas Duffield, director of the Bureau of Vital Records and Statistics of the New York City Department of Health. Helpful criticism and suggestions were made by Mr. Louis Weiner, chief of the Statistical Division, and Mr. Irving Galloway, junior statistician.

† Tabulations prepared by Miss Anne Eisenstadt, clerk, New York City Department of Health.

each caused by one micro-organism that is known to be susceptible to the sulfonamide treatment. In pneumonia, which is caused predominantly by the pneumococcus and beta-hemolytic streptococcus, therapeutic experiments have also shown uniformly striking reductions in case fatality rates that would justify the expectation of marked changes in mortality. The relatively small change may be due to the relatively shorter period since the introduction of potent drugs in 1939.

In others of the tabulated diseases, considerable diversity of opinion persists as to the mode of application, and the amount of effect on the mortality that is to be expected from the sulfonamide treatment. In three of the diseases—measles, scarlet fever, and appendicitis—the sulfonamide treatment was directed not at the original infection but at the bacterial complications commonly associated with death. In each of the three diseases, the complications were due to various micro-organisms which differ in their susceptibility to the sulfonamide drugs. Localized purulent infections often occur which are resistant to the action of the sulfonamide therapy. Reports of therapeutic effects in these diseases have varied considerably, both in the methods employed and in the results. The striking changes in the mortality from measles and scarlet fever following 1937, and in appendicitis following 1940, were therefore not expected by all observers. In the nine remaining disease titles a number of different pyogenic micro-organisms may be present, which vary in their susceptibility to the sulfonamide drugs, and localized purulent complications may occur, which, unless drained, are resistant to the therapeutic activity of the sulfonamide drugs. It is therefore surprising that four of these conditions (phlegmon with acute abscess,

diseases of the ear and mastoid, osteomyelitis and periostitis, and diseases of the pharynx and tonsils) should show a reduction of more than 50 per cent in mortality in the five years following 1937, as compared with the five previous years.

Because of the unexpected variations in the amounts of change in different disease titles, further information is needed to correlate the changes in mortality that have actually occurred with the changes in fatality rates reported following therapeutic experiments. Close correlation would be possible (1) if deaths were classified on the basis of the infecting micro-organism whenever this is known to the physician; (2) if data as to the number of cases were obtained; and (3) if data were obtained on the extent of the use of the sulfonamide drugs—particularly whether those who died received adequate therapy. It would seem advisable to have this information in order to show how nearly the maximum possible mortality reductions were being obtained by the general application of the sulfonamide drugs. In this connection, definite information is needed concerning the extent to which the drugs can be safely used, in the prophylaxis of acute bacterial complications as well as in the treatment of acute bacterial infections.

It is clear from the data presented that the sulfonamide drugs saved thousands of lives annually in New York City in the five years from 1937 through 1941, and that progressive improvement was still taking place in 1941, five years after the introduction of sulfanilamide. The sulfonamide drugs are one of the most potent weapons at hand for the reduction of mortality rates. Thorough study of their rational use, and the extent of their application, may provide a sound basis for even more favorable results.

BIRTH OF AN IDEA

The *New York State Journal*, published at Albany by Allen Eddy to report news from the State Capitol, has the following editorial in its September 7 issue:

"Upon her return from a visit to the United States, Dona Salvadorita de Somaza, wife of the President of Nicaragua, bought up every pawn ticket in her country, and every article so pledged for loans was returned to the original owner. The item bringing this news adds a statement of the obvious, 'there were many happy children and many happy poor families,'

throughout the country as a result of the First Lady's generosity.

"A mystery remains, however. Where did she get the idea? She acted in the matter on her return from the United States. Nobody hereabouts set the example."

It would be interesting to know where the good Dona got the idea for this novel form of philanthropy, but we can think of something even more interesting about it.

Where did she get the money?—*Hempstead Review Star*

TABLE 3—REDUCTIONS IN MORTALITY RATES PER 100,000 POPULATION FOLLOWING INTRODUCTION OF SULFANILAMIDE, IN 14 SELECTED DISEASES

Disease	Average Mortality Rate for 5-Year Periods		Percentage of Reduction	Current Mortality Rate—1941
	Before Sulfonamides 1932-1936	After Sulfonamides 1937-1941		
Erysipelas	2 8	0 5	82	0 1
Scarlet fever	1 1	0 2	82	0 09
Measles	1 4	0 3	79	0 3
Phlegmon and acute abscess	1 3	0 3	77	0 2
Cerebrospinal (meningococcus) meningitis	2 0	0 7	65	0 6
Diseases of the ear and mastoid process	5 1	2 3	55	1 7
Osteomyelitis and periostitis	1 1	0 5	55	0 2
Diseases of the pharynx and tonsils	3 0*	1 4	53	0 6
Pneumonia (all forms)	98 5	60 2	39	45 0
Meningitis (not meningococcus)	2 6	1 6	38	1 3
Abortion with mention of infection	1 1	0 7	36	0 5
Infection during childbirth and puerperium	1 3	0 9	31	0 6
Empyema	1 6	1 1	31	0 7
Appendicitis	14 6	10 3	29	7 5
Total rate (14 diseases)	137 5	81 0	41	59 5
Total number of deaths	9,826	5,996		4,475

* Average for three years 1934, 1935, and 1936

before the introduction of the sulfonamide drugs, when the average population was 7,153,000, had persisted through 1941, when the population was 7,521,000, 10,341 deaths would have occurred from these 14 cases, instead of the 4,475 that were reported—a difference of 5,866 deaths. Pneumonia deaths would have been greater by 4,025, appendicitis deaths by 534, and deaths from the remaining twelve causes would have been greater by 1,307. It has been noted, in Table 2, that downward trends, or marked irregular variations, occurred in the numbers of deaths attributed to some of these conditions. It is therefore not possible to attribute the whole change to the administration of the sulfonamide drugs. The extent of the changes that followed the introduction of the sulfonamide drugs in these diseases for which the sulfonamide drugs are known to be effective justifies the belief that it is, in part, due to such therapy.

In measles and scarlet fever, it is possible to compare the number of cases as well as the number of deaths for the five-year periods before and after the introduction of sul-

fanilamide, to determine whether the decrease in mortality affected primarily the number of cases, or the number of deaths, or both. Table 4 shows that changes in mortality rates for measles and scarlet fever were due mainly to the decreasing numbers of deaths, since no decrease in the reported cases, comparable to the fall in the death rate, occurred. The case fatality rate for measles was 83 per cent less in the five years beginning in 1937 than in the previous five years. The reduction in scarlet fever case fatality rates was 68 per cent. The changes in case fatality rates were progressive during the five years following the introduction of sulfanilamide, and the report for 1941, the latest year for which reports were available, shows the lowest case fatality rate from both of these diseases. Such data are not available for the other tabulated diseases. Hospital reports indicate, however, that the number of cases with mastoid diseases and the number of operations for this condition have decreased. Similar reductions in the numbers of cases may be responsible for a part, or all, of the reduction in mortality in this title, or in other titles for which the total number of cases in the city are not known.

TABLE 4.—REDUCTIONS IN CASE FATALITY RATE OF MEASLES AND SCARLET FEVER FOLLOWING THE INTRODUCTION OF SULFANILAMIDE

Disease	Average for 5-Year Periods		Percentage of Reductions	Current Figures 1941
	Before Sulfonamides 1932-1936	After Sulfonamides 1937-1941		
Measles				
Number of cases	23,325	28,098		79,646
Number of deaths	97	20		25
Case fatality rate	0 41%	0 07%	83%	0 03%
Scarlet fever				
No. of cases	12,731	9,075		7,206
Number of deaths	77	17		7
Case fatality rate	0 60%	0 19%	68%	0 10%

Discussion

In three of the tabulated conditions, it is generally agreed that the sulfonamide treatment is almost uniformly successful and it was expected that marked changes in mortality would be recorded. In erysipelas and meningococcus meningitis, uniformly favorable reports of the results of the sulfonamide treatment have led to general agreement as to the indications for their use and to the expectation that changes in mortality, such as those described, would result. They are

the 14" × 17" paper are all being used for mass surveys. While not so accurate and dependable in all respects, they help greatly in uncovering unsuspected chest pathology. From information thus far available it appears that the 4" × 5" film ranks next to the 14" × 17". Following in order of reliability is the 14" × 17" paper, the 35-mm. film, and the fluoroscope. The errors of these latter methods as compared with 14" × 17" films run from 1 per cent to 5 per cent. The tuberculin test is one way of approaching this problem of looking for tuberculosis, providing that all positive reactors are radiographed.

No tuberculosis control program can be as effective as it should be unless it includes a complete and thorough follow-up system.

A suggested follow-up routine might be:

Age	Retake
18-25	1 year (first time)
	2 years (if pre-employment and first follow-up were negative)
26-30	2 years (first time)
	3 years (if pre-employment and first follow-up were negative)
30-over	
	3 years if negative

Cases that are not included in this routine schedule of follow-up, such as any slightly suspicious films not classifiable, markedly fibrosed, or calcified, or with obviously healed areas, should be checked more frequently, sometimes as often as every month. Contacts should be checked every six months. If three or four successive periodic radiographs are negative and the contact has been removed, the routine schedule could again be followed. Those working on jobs where there is any possibility of hazard (such as exposure to dust, fumes, or vapor) should be checked periodically, usually every six months or every year.

Visiting nurses, calling on all absentees because of illness of over three days' duration, not infrequently bring to the attention of the staff facts concerning the medical history of employees who are absent with an illness that might be caused by or related to tuberculous infection. They should make sure that those employees who are absent from work because they have pleurisy, influenza, or pneumonia are radiographed before returning to work.

Both physicians and nurses must be on the alert constantly. However, such alertness cannot, in itself, discover all the cases of early tuberculous infection which should be discovered.

The administrative details of any tuberculosis control program are of primary importance. Our experience has convinced us that if adequate medical supervision is to be maintained, proper and efficient methods are essential. Accurate bookkeeping is necessary for the early detection of such cases of tuberculosis as may develop and for the control of those arrested cases after their return to work.

Adequate records must be kept to insure the return of employees on the dates recommended for follow-up examination and roentgenogram. A tickler file, maintained by one assistant, is effective as a reminder to send for individuals on schedule for re-examination. Not infrequently failure to establish an early diagnosis or to prevent relapse is due to clerical error or oversight. In supervision of large groups, the most rigid attention to details of record keeping is imperative.

The method of controlling tuberculosis in industry, as discussed above, is more easily and readily applicable to large plants. Wherever the frequent use of radiographs is called for, fairly complete roentgenographic equipment is necessary, and its cost, logically, is more easily absorbed by a large organization. There is no better way of controlling tuberculosis than by the aid of the chest roentgenogram. On the face of it, the cost seems high, but weighed with the cost of taking care of the tuberculous patient where there is no real control, it is not prohibitive. For large groups it is possible to do periodic mass surveys at relatively little per capita cost. The valuable results unquestionably justify the investment.

For the smaller plant of several hundred employees, of which we have a large number in this country, the problem is quite another matter. So far as chest roentgenographic facilities are concerned, this can be done economically only if one of the following schemes is pursued:

(a) A group of plants in a neighborhood can set up a medical service of their own which will periodically provide a chest roentgenogram service. Either a portable outfit would be necessary or some convenient central location could be chosen for a medical department. Joining together in such a plan would probably be the most economical arrangement for each industry.

(b) In some industrial communities physicians have occasionally established a medical service for small employed groups. It is seldom carried out within the plant, but at a central dispensary. This, of course, has its disadvantages inasmuch as employees have to

THE ROLE THAT INDUSTRY CAN PLAY IN THE ELIMINATION OF TUBERCULOSIS

W. A. SAWYER, M.D., Rochester, New York

IN A summary of a "Symposium on Tuberculosis in Industry," held at the Saranac Laboratory in June, 1941, Dr. Leroy Gardner states that the prevalence of tuberculosis in any community or group is determined by the general standard of living and by the number of open carriers. He continues: "It is accepted that the source of the great bulk of infections is a human carrier with a pulmonary cavity. From the public health standpoint the objective is early detection of these carriers, segregation and closure of their cavities. . . . While the home is probably the place of most childhood and some adult contacts, *many primary and more reinfections must occur in the place of work.*"

Obviously, industry has a responsibility in the elimination of tuberculosis. We all know that finding tuberculosis is a question of looking for it. Industry can look for it on a large-scale basis. Machinery for routine examinations of apparently well individuals can be, and in some industries has been, set up with extremely gratifying results. In the Metropolitan Life Insurance Company, with its 14,000 employees, during the last thirteen years new infections at all ages have steadily declined, from 56 in 1928 to 13 in 1940. In the Eastman Kodak Company the incidence of tuberculosis has been reduced from 2.3 per cent in 1921 to 0.5 per cent in 1941. This has been accomplished by radiographs at the time of employment and periodic follow-up films during employment.

The "Symposium on Tuberculosis in Industry" held at Saranac Lake concluded that "Aside from nutrition and social-economic factors, silica was the only other factor which had a recognized effect on susceptibility." Many occupational conditions popularly accepted as predisposing to this disease were reported to be without measurable effect.

Such factors as fatigue, temperature, humidity, trauma, fumes, gases, lead and zinc exposure, and organic dust (from grain and tobacco) were reported as having shown no appreciable effect.

It is interesting to note the following figures reported at the Symposium. In 1911 this

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1942.

Medical Director, Eastman Kodak Company.

disease was the *first* cause of death among wage earners, accounting for 20 per cent of their mortality; today it is *sixth* in importance and is responsible for 6.5 per cent of their deaths.

It will perhaps be helpful at this time to outline a possible program for an industry wishing to take part in the elimination of tuberculosis in its organization and community.

The ideal procedure should include:

1. Chest roentgenograms of all present employees.
2. Chest roentgenograms of all applicants for employment.
3. Periodic follow-up roentgenograms of all employees.

Inability to pursue an ideal program should in no way deter an organization from doing some part of it as a starter. It is not often that full-fledged programs are launched in their entirety. Doing one thing well at the start is enough. The chief point is to have a goal of reducing and controlling tuberculosis and then work toward it step by step.

Obviously, in considering any such program, the first step is to discover the amount of tuberculosis in the present-employed group. This was done by us in the Kodak Company in 1921, at which time 3,280 apparently well adults were examined by means of single chest films and were diagnosed as having either latent or clinically significant tuberculosis. Those diagnosed as positive (2.3 per cent) or suspicious (1.4 per cent) constituted 3.7 per cent of the whole series and were confirmed by subsequent stereoroentgenograms.

The next step is to prevent the possibility of new cases of tuberculosis being added through new employees. This can be avoided by routine roentgenograms of all applicants for employment. In an analysis of 4,640 applicants for employment, examined by this means in the Kodak Company, 0.5 per cent were found to have active or clinically significant tuberculosis.

Consideration can be given to the fact that although 14" X 17" films are considered the most satisfactory and trustworthy method of detecting early and symptom-free tuberculosis, there are other successful and almost as efficient methods.

The 4" X 5" film and the 35-mm. films and

of tuberculosis. He has had long and intensive experience in controlling this disease in one of the large industries of this country. He speaks with authority. It is good to know his views.

The attitude the worker often has toward mass examination of his group for tuberculosis is worthy of repeated emphasis. He forms an important part of industry; so important that at times management is afraid of its own job.

This workingman is greatly interested in health; particularly as it applies to himself, his family, and his community. But to him health is more than freedom from disease; it is also freedom from want and insecurity.

To get this precious all-inclusive commodity for those who are dear to him, he has to pit himself against forces beyond his control—forces that constantly drain his vitality. His side of the fight is as unstable as life itself. On it he has his strength, his skill, an intense desire to care properly and sufficiently for those dependent upon him, and a determination to see through any crisis, no matter how great the cost.

Tuberculosis is one of his strongest and most heartless enemies. It is a foe that endangers family, cuts earning power, and destroys fair dreams. He knows all of this, and he knows there also will be poor provision for the remainder of his family and inadequate rehabilitation—if any.

When he applies for employment, management can, and often does, require him to have a medical examination including a chest roentgenogram. Management may require him to have periodic re-examinations. His attitude toward this medical work will depend on the spirit back of it. If, when disease is discovered, his treatment is sympathetic, the welfare of his family protected, an interest in his return to work shown by word and deed, and, above all, a job saved for him, he will not actively resist the procedure. But let us not fool ourselves; only rarely does he find himself in such an ideal situation.

The degree and amount of education that a worker has make no difference in his resistance to mass examinations. A skilled employee has the same instinctive fear. Professional workers such as teachers voice the same objections.

To make him accept these examinations, he

must feel they are a benefit and not a danger. To be sure, he is interested in good public health in his community. He wants good air, clean water, nourishing food, and milk free from infection, for himself, his family, and each and every one of his neighbors. These benefits he is willing to vote and pay for. But, somehow, tuberculosis is different. He realizes it is best to have none of it around, but he feels it is impossible for him to contract it. The last time he went to his doctor he received a clean bill of health, and has felt exceptionally well ever since.

Obligatory examinations by management are particularly odious if the findings are not to be made available to him. Voluntary examinations by public health agencies, clinics, and hospitals are not so difficult to accept. Those by his own union he knows are conducted in a way to protect his interests, and he finds it easy to support them.

Unions definitely recognize the value of fighting tuberculosis and of discovering it early. But they want the rights of the worker protected and the responsibility for the disease placed against society as a whole. They do not want the worker penalized; they want him and his family cared for adequately until the chapter is closed one way or another. Some unions even insist on a physical examination as a requirement for membership.

Management, by mass examination of its employees for tuberculosis, sees the elimination of some of the unfit from its plant, and the prevention of further spread of the disease. By pre-employment examination, it can prevent many cases from becoming liabilities to the firm. It sees a medical department as a means to higher profits and lower compensation premiums.

We have a willingness for these examinations on the part of all participants—the worker, the unions, management, capital, medical profession, health authorities, and the community. No one argues against their desirability and their value. There are arguments, however, as to the methods to be employed. To meet these, the next step has to be planned around the conference table with all parties present, each one willing to consider and evaluate points of view different from his own, as long as the worker is protected and given a fair deal.

USED AND DISCARDED X-RAY FILMS NEEDED

Bundles for America, as part of its "Salvage for Defense" program, has organized a Salvage X-Ray Division. The Division has the approval of the War Production Board and members of the President's Committee on War Relief Agencies. It is the purpose of this division to collect used and discarded x-ray films (no dental film), and sell them to obtain revenue with which to carry on the work of the organization in supply-

ing the needs of the men in the armed forces.

If you have any used or discarded x-ray film which you may care to donate to Bundles for America, will you please telephone Plaza 5-9100 or write to Bundles for America, Inc., 681 Fifth Avenue, New York City. Your contribution will be called for at your convenience.

(Signed) MRS. ROBERT B. BRADLEY
National Director, X-Ray Salvage Project

travel to the center for their roentgenograms. However, it does provide a control.

(c) A third arrangement is one that could be set up by a local hospital or county tuberculosis sanatorium, with or without the aid of the public health officials. For applicant examinations a visit could be made to the institution. For periodic check-ups a portable outfit would solve the need.

Inasmuch as tuberculosis is a communicable disease and there is great effort being made to bring it under control by 1960, is there any valid reason why public health officials should not put some such plan into effect?

(d) Private physicians in industrial neighborhoods sometimes have facilities that will take care of applicant and periodic roentgenograms. Unfortunately, this type of setup does not lend itself as readily to the convenience of a small plant.

It must be evident from the above that there is no valid medical reason why the control of tuberculosis cannot be carried out for a small group. It is largely a matter of a decision to do the job, using some of the facilities at hand, gradually extending them when necessary.

Now more than at any other time, because of the pressure of work, longer hours, and crowded and unsatisfactory living conditions, there is reason for extra precaution so far as tuberculous infection is concerned, both in large and small industries. Many individuals will have to be employed whose health is substandard and who should be considered more susceptible to such infection. Therefore, there should be more effort made to extend and maintain proper health supervision, especially in regard to the detection and control of tuberculosis.

Discussion

Dr. B. L. Vosburgh, *Schenectady, New York*—Dr. Sawyer has told you what part industry can play in combating tuberculosis. He has described the methods used at the Eastman Kodak Company and I am sure you have been impressed with their success. When their tuberculosis incidence has been reduced from 2.3 per cent to 0.5 per cent it has not happened by mere chance. Such an accomplishment represents the culmination of masterful planning, a great deal of persistent effort, and the vision of worthwhile spending.

In discussing this paper, I shall make three points:

1. Some lung field-inspection method is needed in industry.
2. The working environment is implicated.
3. There is a public health lesson to be learned.

You will recall that Dr. Sawyer explained in some detail the plan in operation at his industrial plants—namely, an x-ray of the lungs of every applicant when he is engaged and then periodically (according to age and condition).

Other good visual field methods are the 4" X 5" photograph of the fluoroscopic image, the 14" X 17" paper film, the 35-mm. photograph, and the fluoroscopic image itself. These methods are listed in the order of their efficiency. They lend themselves admirably to the search for minimal tuberculosis.

The Metropolitan Life Insurance Company has asked recently, "What are the signs and symptoms of early tuberculosis?" Their answer is, "There aren't any." At first that answer is a bit shocking. The medical textbooks used to list quite a few signs and symptoms under this heading. For example, cough, slight expectoration, slight loss of weight, slight afternoon fever, etc. Now we know that they were the story of moderately advanced disease. We know also that by the time patients consult their physicians because they are ill with pulmonary tuberculosis, only rarely can the disease be classified as an early case.

Dr. Sawyer has presented a set of conservative figures representing the cost of curing the various stages of tuberculosis. The curve rises sharply when minimal disease has gone on to advanced pathology. And let us not lose sight of the fact that increased costs simply parallel prolonged suffering and greater losses in manpower.

Industrial manpower is being conserved more and more by our greater knowledge of engineering and medical control of silicosis. This is pertinent here, as the speaker has pointed out, because more silicosis invariably means more tuberculosis. On the other hand, it has been shown quite clearly by Gardner and others (and this is important, too) that dusts other than silica dust are relatively harmless as agents predisposing to tuberculosis. Employers on jobs that do expose workmen to silica dust are now recognizing their responsibility to reduce the dustiness to a safe concentration and to x-ray the lungs of all exposed workmen both when they are hired and at regular intervals thereafter.

If some industries have been x-raying or visualizing the lungs of all workmen regularly and by these methods have been able to reduce their tuberculosis rates almost to an irreducible minimum, and if it is true that there aren't any signs and symptoms in early tuberculosis, then it seems to me there is a public health lesson to be learned. The entire public should be educated to have their lung fields inspected at regular intervals. It only remains for the master minds in public health to perfect a plan of procedure that will fill the bill.

Dr. Ezra Bridge, *Rochester, New York*—Dr. Sawyer's paper gives a broad, clear view of the role that industry can play in the elimination

contributed to the lack of tuberculin testing, have been overcome since the reliability of the "patch test" has been established.

The decline in the death rate from tuberculosis in upstate New York from 74.6 per 100,000 population in 1926 to 33.7 in 1940 is most gratifying. This is not only a reflection of the improved social and economic conditions but is also a tribute to the able and efficient administration of our State Department of Health. However, in appraising the present figures, circumstances as they now exist make any forecast of the future difficult. The radical changes which have occurred in our social existence during the past few months may adversely affect the continued decline in tuberculosis. Unless the present tempo of tuberculosis control is accelerated, the increased physical strain to which so many are being subjected may easily result in an increase in the incidence of the disease.

Many possible sources from which the disease may be spread to healthy contacts are still existent. If they are investigated effectively, the incidence of tuberculosis can be reduced to meager proportions. Mass x-ray examination of those living in sections that have a high incidence of the disease is always productive of new or fresh cases. This is a public health procedure and of necessity should be carried out by health authorities. The private physician, however, can also be of material assistance if he attacks the problem in his own practice. He should start with the individual family. In adults an x-ray examination of the chest should be as much a part of any periodic health examination as a urinalysis, a blood count, a blood pressure determination, or a blood Wassermann. It might prove to be even more informative. Along with the Schick test and other routine procedures, the "patch test" for tuberculosis should be included every few years, as part of the yearly check-up in children. It, also, will be informative. Positive reactors should be x-rayed subsequently to determine the phase of tuberculosis that is existent.

Tuberculin testing as part of a complete examination is a matter of routine in most children's hospitals. Many important clues in tuberculosis control are unearthed through this procedure. In general hospitals, however, only the occasional adult has a chest x-ray as part of his general examination. During the course of a year in the wards of a general hospital, there must be many cases

TABLE 1.—TUBERCULOSIS AMONG TEACHERS—1936

	Number Studied	Cases of Pulmonary Tuberculosis	Incidence of Pulmonary Tuberculosis

of early tuberculosis that escape detection because of the omission of a chest x-ray.

One of the most encouraging features of the entire program of tuberculosis control has been the subject of tuberculosis as a school health problem. Large groups of apparently well students have been examined by means of the tuberculin test and chest x-ray. During the school year of 1940-1941 more than 200,000 college boys and girls were examined in this manner. This, in addition to being an excellent public health measure, is an educational project of the greatest importance. It is a lesson in public health which stresses the significance of tuberculosis and its control and should result in saving many lives.

There is still existent an important phase of tuberculosis as a school health problem which has not been attacked as assiduously as possible. Very little is being done to protect the student from possible exposure to the teacher who has active tuberculosis. Lees⁴ reports that the incidence of tuberculosis in teachers, the majority of whom are in that age group in which tuberculosis takes its greatest toll, is about 2.15 per cent (see Table 1). It is estimated that there are nearly a million teachers actively employed in the schools in the United States. It is, therefore, fair to assume that there are approximately 20,000 teachers with active tuberculosis who are in our schools and in daily contact with children. It is a potent source from which the disease may be spread. The contact between the child and the tuberculous teacher is quite analogous to exposure to the disease in the home. There is ample evidence to show that the incidence of tuberculous infection of children in a class taught by a teacher with the disease may be several times greater than the average rate for the community. Only twenty states have definite laws that require teachers to have yearly examinations including an x-ray, or a tuberculin test and an

CONTROL OF TUBERCULOSIS IN CHILDREN BY PREVENTION OF ITS SPREAD THROUGH CONTACT

WILLIAM J. ORR, M.D., Buffalo

ONE of the great tragedies of tuberculosis is that the new recruits who are taken into its army are drafted so frequently from the youth of our nation. Tuberculosis has done more to undermine the manpower of our country than any other single disease. Although it no longer ranks first on the mortality lists as a cause of death, it still exacts a greater toll of victims between the ages of 15 and 25 than any other malady. It is generally considered a disease of adult life. It must, however, be pointed out that in many instances the infection was acquired during childhood even though the active disease did not become manifest until late adolescence or early adulthood. Every year thousands of children become infected with tuberculosis through contact with adults who have the disease. Rarely is it spread by children. These remarks are not new. They are familiar to all of us. Yet, year after year, the same vicious cycle in the spread of the disease continues to occur. It is equally well known and apparent to all of us that if we intend to control tuberculosis by prevention of its spread through contact, one of the most effective means is safeguarding the child population from exposure to the disease. The soundness of this statement cannot be questioned. Veterinarians, in the eradication of bovine tuberculosis, have set an excellent example. Cattle are now born and live in an environment free from the disease. Certainly we should provide the same opportunities for our children.

The ultimate fate of a child with primary tuberculosis is still a controversial subject. Wallgren¹ and Levine² state that children under 6 or 7 years with positive tuberculin tests and no clinical tuberculosis are not rendered more susceptible to reinfection tuberculosis from an exogenous source. Opposing these views, Ch'ui, Myers, and Stewart,³ in a follow-up for a period of ten years of 446 children with positive tuberculin reactions and no clinical pulmonary lesions compared with 772 children who had negative reactions, report that the incidence of reinfection tuberculosis in the group of positive reactors was nine times that which occurred

in the negative reactors. The ratio of the mortality for the positive reactors and the negative reactors was 38 to 1. The average age at the first examination for the positive reactors was 7 years and for the negative reactors was 6.6 years. It is also generally agreed (except in infancy and very early childhood) that most children successfully resist their first infection of tuberculosis, and usually no serious consequences develop in later life. Nevertheless, it should be remembered that the disease may and does spread from an endogenous source as well as from an exogenous one. Regardless of the existent divergencies of opinion, there is one fact which is absolutely indisputable, and it should be driven home. There can be no tuberculosis without the presence of tubercle bacilli.

An existent fallacy which has helped to confuse the problem of tuberculosis control is that primary tuberculosis acquired during childhood is almost to be desired, as it renders an immunity to any future manifestations of the disease. Some of the indifference and complacency regarding the problem of childhood tuberculosis may be attributed to this erroneous impression.

Many private physicians fail to appreciate fully the value of tuberculin testing as an aid in diagnosis and also as a screen with which the tuberculous and nontuberculous population may be separated. There are a great number who never employ it. Others doubt its value or use it only occasionally. Very few, indeed, ever give it general usage. The tuberculin test is a highly specific diagnostic procedure. Its widespread use should serve as a valuable weapon in the eradication of tuberculosis. Physicians throughout the country should be encouraged to use it more frequently in their practice and in public health work.

A positive reaction is not only a diagnostic aid, but it may also indicate that someone in the immediate environment of the patient has active tuberculosis.

In the past, a supply of freshly diluted tuberculin was not always available to the physician, and the public frequently objected to the injection of a tuberculous-like substance. These difficulties, which may have

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1942.

under the fluoroscope, an x-ray of the chest is made.

5. Sputum examination.
6. Smear for gonorrhea.
7. Suspicious smears are followed by a culture for gonococci.
8. A blood test for syphilis.

Ninety per cent of all examinations are done by the Department of Health without charge. In a communication from Dr. Exner, he stated that during 1941 they discovered 30 new cases of tuberculosis. He further stated that the ordinance had met with little or no opposition in the community.

Early in 1941 the Tuberculosis Association of Washington, D.C., approached the problem of x-ray examination of domestic employees. Physicians, churches, insurance companies, employment agencies, employer groups, public health nurses, clinics, and others cooperated in the educational program. During this time, radio programs were presented, and the newspapers carried complete stories on the project. Civic clubs, luncheon clubs, etc., were appealed to with three-minute speeches on the subject. An advisory committee, similar in nature to the one now established in New York State, supervised the campaign. Examinations were made of 357 individuals, from which 20 cases of active tuberculosis were discovered. Detroit, St. Louis, Minneapolis, Montreal, and other cities have also conducted educational programs which have been successful in discovering new cases of the disease. Similar campaigns should be conducted throughout the United States, not only for their importance as a public health measure, but also for their educational value. They serve as an excellent medium through which the general public may learn of the ways and means of protecting themselves from exposure to tuberculosis. Physicians must be taught that a thorough physical examination must be supplemented with a tuberculin test and an x-ray examination of the chest if they are to rule out tuberculosis.

Almost always, it is the adult with active tuberculosis who sows the seed that frequently finds its soil in the child population, who in turn represent the harvest when they reach adulthood.

We in New York State are well organized to conquer tuberculosis. The campaign is now under way. Let us keep moving toward the goal: "No Tuberculosis by 1960."

Discussion

Robert E. Plunkett, *Albany*—Dr. Orr has stressed a fundamental point in discussing the public health aspect of tuberculosis. He states that an offensive rather than a defensive program is necessary. I would qualify that statement by saying that we must build up a better defensive service and augment it with an all-out offensive program.

If infection and reinfection are to be prevented—and this is essential in controlling any communicable disease—it is necessary to find the cases, or foci, and to segregate, treat, and educate patients who have the disease.

While it is necessary to continue placing emphasis on the importance of examining contacts as a case-finding measure, this alone will not bring about the desired results. After twenty years' experience in conducting consultation chest clinics, we find that the yield of new cases of tuberculosis is practically the same among patients referred by physicians because of the presence of symptoms or some other indication of the need for a chest x-ray as it is among contacts. This yield varies with the ages at which patients were examined for the first time at our state tuberculosis hospital clinics. In the age group 15–24, the average percentage yield for the past three years among contacts was 2.6 as compared to 1.9 among the others referred by physicians. In the age group 25–44, the respective yields were 3.8 and 3, while among those 45 and over the yield was 4.7 for the contacts as compared to 5.9 per cent among the others. The yield for all ages over 15 was 3.7 for contacts and 3.4 for non-contacts. Moreover, quoting Dr. Ralph Horton, the yield among contacts with symptoms is greater than the yield among contacts without symptoms.

Among the lessons to be learned from this experience is the realization that we must urge physicians to be more and more alert to the possibility of tuberculosis, not only in contacts but particularly in patients presenting symptoms. These persons should have the benefits of x-ray and sputum examination without delay.

Should we achieve the optimum in this consultation type of service, there would still be left in every community many hidden cases of tuberculosis. To discover these cases is even more the job of the health department, and a more offensive type of attack is indicated. We must not wait for these persons to go to the doctor or the clinic; this service must be brought to them. In other words, health departments must carry on a vigorous campaign of case-finding in all sections of the population in which the disease may be lurking and insidiously waiting for an

TABLE 2.—DEATH RATES PER 100,000 FROM TUBERCULOSIS OF RESPIRATORY SYSTEM OF 11,082,110 GAINFULLY OCCUPIED MALES, 15-64 YEARS OF AGE, BY BROAD AGE GROUPS, ACCORDING TO SOCIAL-ECONOMIC CLASS AND COMPONENT OCCUPATIONS

(10 Selected States, 1930)

Cooks				172.2
Unskilled workers	95.7	193.5	229.3	183.1

x-ray, to rule out the possibility of the disease. In other states, only local rulings affect this problem. There are, however, many communities in which tuberculin testing and x-rays play no part in pronouncing teachers free from tuberculosis. Some large centers require an examination of student teachers and a certification of health for teachers renewing their licenses. This is obviously inadequate. A single pronouncement of good health may easily establish a false sense of security in an individual. As a result, later on, warning signs of ill health are apt to be disregarded. It is difficult to offer an effective solution for the problem of annual health examinations of school teachers. There is only one answer. It should be done. There are, however, two points of view as to the proper method of approach. Some authorities advocate the enactment of compulsory legislation. This, perhaps, is the logical and ultimate solution, as the danger would be eliminated quickly and on a large scale. There are others who advise an educational program which would popularize the procedures in the individual community and eventually lead to the enactment of regulations generally. Perhaps the same goal may be attained by either method.

Data collected in 1930 indicated that the incidence of tuberculosis was greatest in individuals engaged as cooks, waiters, food-handlers, and domestic servants (see Table 2). Although the death rate from tuberculosis in these respective groups has undoubtedly fallen during the past twelve years, that unquestionably represents one of the most important sources from which tuberculosis is spread. A large percentage of these people are employed in private homes where they have intimate contact with the members of

the household, especially with the children. Yet, despite this vital information which is now twelve years old, only a surprisingly few communities have made any effort to correct, effectively, this situation. Why this has not been done is one of the enigmas of tuberculosis control. The project should rank among the first for consideration. It has been reported that from 5 to 10 per cent of individuals in these component groups have active tuberculosis. A food-handler is examined for rashes, gonorrhea, and syphilis; a stethoscopic examination is done on the chest, but rarely is any attempt made to certify that the individual is free from active tuberculosis by having an x-ray examination of the chest. Active tuberculosis is equally as communicable as the conditions mentioned would indicate and should be ruled out.

A domestic when seeking employment in a private home must produce references pertaining to her morals, her ability to cook, serve, assume other household responsibilities, and, if necessary, administer to the needs of the children. If these are lacking or subject to question, the chances of her finding a position elsewhere are extremely poor indeed. Every housewife expects these qualifications of any applicant, but practically never does she inquire into the health of the job-seeker and ask for a medical certification that no communicable diseases are present. Again, there are two avenues of approach by which this problem may be effectively attacked: one is legislation and the other is education. New-ark has an ordinance requiring the examination of all domestic employees, which has been in effect since 1930. It states that no person shall work as a domestic servant, nor shall any person, firm, or corporation employ any person as a domestic servant unless such person has filed with the Department of Health a medical certificate stating that such person is free from tuberculosis and other contagious or communicable diseases. A certificate of good health is issued to the applicant, and it is effective for six months. At that time the person must be re-examined. Any person or firm violating this ordinance is subject to a \$25 fine for the first offense and \$50 for each subsequent offense. The following procedures are included in the routine examination:

1. A general inspection of skin, mouth, throat, nose, etc.
2. A stethoscopic examination of the chest.
3. A fluoroscopic examination of the chest.
4. When suspicious findings are observed

SULFONATED HYDROGENATED CASTOR OIL AS A DETERGENT AND OINTMENT BASE

SHEPARD QUINBY, M.D., and GEORGE W. FIERO, PH.D.,* Buffalo

SULFONATED oils have long been used industrially, but it is only in recent years that their dermatologic significance has been studied. Early workers have reported them to be irritating, but it is now known that this irritating action was the result of using a technical product which was not specially prepared for medicinal purposes. Sulfonation (or, more correctly, "sulfation") of oils is accomplished by a reaction between unsaturated oils and sulfuric acid. Failure to remove or neutralize the excess acid and other impurities, as well as the use of these oils in too concentrated a form, may be the chief causes of the irritation previously reported.

The principal dermatologic use of sulfonated oils has been as detergents in those cases of dermatitis in which soap was considered to play an important causative role. Sulfonated oils were recommended by Blank,¹ Lane and Blank,² and Jordan, Dolce, and Osborne.³ They have been found to defat the skin and leave it too dry. This is overcome, however, as pointed out by Blank, by reducing their concentration through the addition of liquid petrolatum. Sulfonated oils have the disadvantage of being liquids and not producing a lather.

Eczematization caused by soaps has been reported by many investigators, and it is commonly met with in both industrial and household cases. Soap solution is always alkaline because of the hydrolysis of the weak fatty acid by the strong alkali. Doubtless this alkalinity, if not a primary irritant, paves the way for the allergic or irritating action of the other fraction of soap—namely, that of the lower fatty acids. Blank has shown that the lower fatty acids are more active sensitizers than are those of higher molecular weight. However, lower fatty acids are quite important in commercial soaps since they produce greater lather, particularly in hard water, than do the higher fatty acids.

Soap substitutes employed today are of three types: (1) untreated vegetable or mineral oils, (2) sulfonated oils, and (3) the newer

wetting-agents. The use of untreated oils is unsatisfactory in that they are not active detergents, cleanse only mechanically, and are unpleasant to use. Jordan, Dolce, and Osborne report favorably on new wetting-agents—lauryl sulfoacetate and aryl alkyl sulfonate. Other wetting-agents have been suggested, such as sodium lauryl sulfate. These substances are solids, produce a lather, and are active detergents. They possess the disadvantages, however, of defatting the skin, and when used in the higher concentrations they apparently have a relatively high index of sensitization.

Sulfonated, hydrogenated castor oil⁴ (hereinafter abbreviated "SHCO") differs from all other sulfonated oils. Catalytic hydrogenation of most vegetable oils results in the production of a solid containing chiefly stearin (glyceryl stearate) with very small amounts of lower fatty acid/glycerides, such as palmitin and myristin. Castor oil, however, differs from the other commercial vegetable oils in that it contains chiefly ricinolein instead of olein, linolein, etc. Ricinolein, unlike olein and other fatty acid glycerides, possesses a hydroxyl group. It is this difference in chemical composition which gives castor oil its peculiar properties. Hydrogenation of castor oil produces hydroxystearin instead of stearin. Thus hydrogenated castor oil is entirely unlike other hydrogenated oils—physically, chemically, and pharmaceutically.⁵ It has a much higher melting point (86 vs. 63 C.), has unusual solubilities, differs in consistency, and, because it possesses the hydroxyl group, is capable of sulfation. Its molecular weight being much higher than that of other hydrogenated oils (hydroxystearic acid 300.24; stearic acid 284.24), it should result in a lower index of sensitization. This assumption is substantiated by Blank's investigation of various fatty acids in which he seldom found sensitization with ricinoleic acid.

Sulfonated hydrogenated castor oil,† unlike other sulfonated oils, is not a liquid, but a soft solid, possessing the following characteristics:

Melting point	41.5 C.
Softening point	30.0 C.
SO ₃ content	10.0%

† Manufactured by National Oil Products Company, Harrison, New Jersey.

opportunity to assume the offensive against the individual, the family, and the community. Industrial workers, domestics, and members of families in the lower economic brackets of our social structure are the most vulnerable subjects among whom to carry on such a campaign.

If we are to obtain appropriate segregation of more tuberculosis cases in hospitals or sanatoriums, we must develop a more direct attack against the social, industrial, and economic factors which are constantly contributing to the spread and the development of the disease. Problems of housing, job security, and family security (especially when the wage earner is stricken) are some of the fundamental influences which must be combated. The taxpayer is paying dearly because of complacency and indifference regarding this problem. No cheaper or better public health insurance can be bought than through the expenditure of more public funds to provide the all-out essentials for case-finding, hospitalization, and domiciliary control.

Positive methods in dealing with tuberculous lesions are becoming more conspicuous in our therapeutic program. Surgical measures which basically are active and positive forms of treatment are more and more being used to augment

the passive expectancy form of treatment usually embracing only bed rest and good food.

May I close by quoting from the paper read at the 1910 annual conference of sanitary officers of New York State by Mr. Charles Fetherolf, at that time a member of the staff of the New York State Department of Health:

"The struggle against tuberculosis must be a struggle against the sweat-shop, crowded tenements, long working hours, small wages, and against everything that tends to reduce one whit the sum total of human happiness. Therefore, the fight against tuberculosis means progress, for progress is truly measured by the increase of human happiness. . . .

"The campaign against tuberculosis is a campaign for popular education that must reach all. Official action is urgent, but it awaits its master—the public."

Let us, therefore, use to the fullest every possible method of informing the public regarding the prevention of this disease. Health departments through education, practice, and demonstration—practicing physicians by clinical practice and participation—related agencies through cooperation, can, when working together, succeed in routing this disease.

Prize Essay

THE Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, May 3, 1943, in Buffalo, New York. This prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The following conditions must be observed:

Essays shall be typewritten or printed, with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win the prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than March 1, 1943, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York City.

CHAS. GORDON HEYD, M.D., *Chairman*
Committee on Prize Essays

the other hand, hydrophilic ointments have the practical advantage of absorbing these secretions. Unlike lanolin or cholesterol-petrolatum ointments which produce water-in-oil emulsions, sulfonated hydrogenated castor oil-petrolatum ointments produce oil-in-water emulsions. The distinction is of great importance, since it is well known that water is more readily absorbed by an emulsion where it is the continuous phase (oil-in-water) than where it is the discontinuous phase (water-in-oil). Moreover, water would be more readily evaporated into the air from an oil-in-water emulsion than from a water-in-oil emulsion.

Pharmaceutically, sulfonated hydrogenated castor oil ointments were found very easy to prepare, with few (if any) incompatibilities. Substances which are often difficult to incorporate, such as tars, balsam of peru, salicylic acid, etc., may be readily incorporated into this base. It was used as a base for all of the official ointments and many unofficial preparations without encountering a single incompatibility.

The emulsified preparation was likewise found to be an excellent vehicle. The following substances were incorporated and made very satisfactory ointments: ammoniated mercury, belladonna extract, Burow's solution, benzoic acid, boric acid, calomel and colloidal calomel, calamine and neocalamine, camphor chrysarobin, coal tar (crude and washed), oil of cade (juniper tar), rectified oil of birch tar (oleum rusci), phenol, pine tar, red oxide of mercury (cinnabar), resorcinol, sulfadiazine sulfanilamide, sulfathiazole, sulfur, zinc oxide, etc. Like most emulsified ointments, it was not compatible with high percentages of salicylic acid.

Laboratory experiments using the FDA agar-plate method were carried⁸ out to compare the bacteriocidal property of antiseptic ointments prepared from the official base SHCO, SHCO and petrolatum, and the emulsified base. While in all instances the addition of SHCO resulted in a more highly efficient antiseptic ointment, those ointments prepared with the emulsified base were the most effective.

The use of wetting-agents in ointment bases has been suggested. There is considerable controversy as to their value. It has been demonstrated that much greater penetration is obtained when an active wetting-agent is incorporated into an ointment. It is questionable if this is desired in most skin disorders. Certainly it should not be recom-

mended for all ointments. Making the keratin permeable reduces its normal protective function and probably would make the skin more vulnerable to allergens. This is particularly true if the medication happens to be a substance with a relatively high index of sensitization, such as mercury. If sensitization is obtained in an ointment of extremely low penetration, such as petrolatum, one would anticipate not only a greater incidence but a much more severe and prolonged reaction if the allergen were used in an ointment of deeper penetration. It is possible that the allergic action of soap is partially due to the fact that soap is an excellent wetting-agent and may thus make the skin more permeable to the allergenic lower fatty acids. Sulfonated hydrogenated castor oil possesses very mild wetting properties. Laboratory tests employing the standard wool yarn wetting properties indicate that a 2 per cent solution requires 250 seconds to wet, whereas a similar solution of soap wets in 2.5 seconds and an 0.5 per cent solution of Aerosol OT wets it instantly.

Summary

Sulfonated hydrogenated castor oil was found to be an excellent ingredient of detergents and ointments. Patch tests on 100 patients and clinical observations of its use on 300 cases indicate that it has a very low index of sensitization. An emulsified cream is recommended as a detergent and ointment base. A mixture of sulfonated hydrogenated castor oil and petrolatum forms a hydrophilic ointment base which is compatible with practically all medicaments.*

The melting and softening points make it quite satisfactory for application to the skin. The pH is extremely important since it coincides with the pH of the skin, as reported by several investigators.⁶

The early clinical use of the product as a soap substitute revealed that while it did not prove irritating and its detergent properties were satisfactory, it did possess the disadvantage of having a sticky consistency. Unless thoroughly removed from the skin by the liberal use of water, it left the skin so sticky that its use as a detergent was psychologically unsuitable. To overcome this objection, various diluents, such as carbitol, glycerin, petrolatum, liquid petrolatum, vegetable oils, etc., were used.

The most satisfactory means of overcoming this objectionable feature of the soap substitute is in the utilization of its properties as an emulsifying agent. Satisfactory emulsions were obtained by using petrolatum, glycol esters, and water. As a result of investigating forty-five such preparations,⁷ the following formula was evolved:*

Sulfonated hydrogenated castor oil	20%
Diethylene glycol monostearate	10%
White petrolatum	30%
Water	40%

The resulting emulsion is a white cream with a consistency approximating that of cold cream. Although it contains petrolatum, it is not excessively greasy and is free from the original sticky quality.

The clinical use of this preparation as a soap substitute has been observed in 300 cases, the majority of which belonged to the dermatitis-eczema group (Table 1). While soap was considered to be the causative factor in only a small percentage of the cases, the majority were of such a nature that it was thought that the continued use of soap would prolong the irritation even though the direct cause had been eliminated. In evaluating the use of this product in these cases, three factors were borne in mind: (1) Was it irritating? (2) Was it a satisfactory detergent? (3) Was the product psychologically agreeable to the patient?

In only one of the 300 cases was a distinct sensitivity observed. This was in a boy 10 years of age who had a low-grade dermatitis

of the face. A few patients in whom irritation had been noted from the use of other sulfonated oils or wetting-agents were able to use this product with impunity.

Patch tests with sulfonated hydrogenated castor oil, undiluted and diluted as recommended above, were carried out on 100 routine hospital patients. These tests were applied on apparently normal skin of the upper back and were left on for forty-eight hours. In only one case was a positive test observed. This patient reacted to undiluted SHCO and the emulsion. So far, our experience indicates that sulfonated hydrogenated castor oil is not irritating and that it possesses a low sensitizing index.

Judging from its practical use, its detergent properties compare favorably with those of other sulfonated oils. Since the emulsion is of creamy consistency, its use as a substitute for shaving soap was found to be excellent in those cases of dermatitis involving the face. When used as a detergent on the scalp, it was readily washed out and, unlike soap, did not leave the scalp objectionably free from oil. The property of leaving a trace of oil on the skin seemed to be especially helpful in protecting the skin against chapping which often results from the use of soap in the winter months.

Use as an Ointment Base

Being miscible with water, sulfonated hydrogenated castor oil has been found to be an excellent component for ointment bases. Used alone, it is quite sticky and therefore desirable only when such adhesiveness is indicated. Its greatest use is with petrolatum, with which it makes an excellent nonsticky ointment base when used in quantities of 25 to 50 per cent. The resultant ointment is hydrophilic and may be readily washed from the skin with water. Being a hydrophile ointment, it is particularly indicated where there is excessive perspiration or serous discharge. When a hydrophobic, petrolatum ointment is used in such cases, it not only tends to dam back secretions, but the aqueous fluid also tends to form a barrier to the ointment. On

The hydrophilic oils are more acceptable substitutes, although they, too, are found irritating to skin in some cases, and are not as satisfactory cleansers as soap. Because they are not soap and fail to give the satisfaction that goes with cleansing by a heavy lather emulsion, they will displace soap only when all soaps have proved deleterious and this personal experience or professional advice makes a substitute for soap imperative. This still provides the inspiration to study variations in soap mixtures for at least a partial solution of the "soap problem."

Such a partial solution has been offered in superfatted soap. It is difficult to judge the degree of success achieved, chiefly because in the many products available the amount and character of the superfatting cover a wide range and the investigator is usually in the dark as to the exact nature of the soap mixture studied. Furthermore, some dermatologists assume that superfatting aims at overcoming the excessive defatting of the skin by the detergent action of soap but that it fails in this purpose, since one cannot expect to effect emollient and detergent action at one and the same time. This reasoning implies acceptance of the judgment that the too thorough detergency by soap may cause irritation of the skin. This may be true for the group who complain that soap dries and roughens their skin; at any rate, they definitely represent the ideal test group for the study of soap mixtures in the class of superfatted soaps.

The "soap habit" involves the use of soap in solid form and with good lathering properties, among other things, and the need for maintaining these qualities has effectively restricted variations in the character of the superfatting creams. Definitely, it has kept at a minimum the amount of added oil these mixtures could contain, since the soap must not only be solid but also must have adequate hardness. I feel that most superfatted soaps contain a minimum of added oil and that most superfatting is in the form of grease; by reason of this the complete possibilities of soap as a source of emollient agents has not as yet been canvassed.

Pursuing this idea I enlisted the services of a soapmaker and a satisfactory soap was processed that contained over 10 per cent of free vegetable oil, was safe against rancidity, had excellent lathering properties even in hard water, was of satisfactory hardness, and contained a typical fragrance. This soap was tried on the group, chiefly women, who

TABLE 1.—DIALYSIS EXPERIMENTS WITH SOAPS
(Using "Gut" and Collodion Bag Membranes)

Soap Sample	pH of 1% Soap Solution in Distilled Water	pH of Diffusate After 1 Hour of Dialysis	pH of Diffusate After 18 Hours of Dialysis
Laundry 1	10.0	10.0	10.0
Laundry 2	9.0	8.5	8.5
Laundry 3	9.5	7.5	9.0
Laundry 4	10.0	10.0	10.0
Toilet 1 (S)*	9.5	7.5	7.5
Toilet 2	9.2	7.5	7.5
Toilet 3 (S)	9.0	7.5	7.5
Toilet 4	9.0	7.5	7.5
Toilet 5 (S)	9.0	7.0	7.0
Toilet 6	9.2	7.0	7.0
Toilet 7	9.0	7.5	7.5
Toilet 8	9.5	7.5	7.5
Toilet 9 (S)	9.5	7.0	7.5
Toilet 10	9.5	7.5	8.0

* (S)—Superfatted.

claimed that the skin of their faces and hands would not tolerate soap. Another dermatologist and I acquired clinical experience with this soap, and the responses from the group on which it was tried were completely satisfactory, though many in the group had tried superfatted soaps and had found them unsatisfactory. The subjects, in expressing satisfaction with this experimental soap, were impressed by its oily content and with the emollient action therefrom.

On the basis of its content, this experimental soap may justly be called "oleaginous soap," in contrast to "superfatted soap." It is evident to me from this experience that much can yet be done by way of soap to help solve the "soap problem."

Discussion

Dr. Eugene F. Traub, *New York City*—Perhaps because of my long association in dermatology at the University of Vermont where "winter" eczema is decidedly prevalent, I was one of the first to gain some publicity as an advocate of less frequent soap-and-water bathing. None of us could fail to observe that most eczematous eruptions, regardless of their causation, were generally worse in the winter or cold weather and would clear up practically entirely in the summer. Undoubtedly, many factors contribute to such a condition, including the drying effects of steam heat, extreme changes of temperature between the out-of-doors and indoors, the sensitizing action of fungus infections, and, lastly, the deleterious effects of soap and water.

As Dr. Sharlit has indicated, most soaps have a pH somewhere between 9 and 10. From experiments performed by Blank and others we learn that there are two chief irritating factors resulting from the hydrolysis of soap. The alkalinity, if not a primary irritant, at least may pave the way for an allergenic action of the fatty acids. The chemical character of water must also be considered because soaps are not infrequently modified, especially through the increase of lower fatty acids, to produce more lather in hard

SOAP AND THE "SOAP PROBLEM"

HERMAN SHARLIT, M.D., New York City

JUDGING from current publications, soap has come to the fore as a dermatologic problem. While the problem is not new or the result of any recent changes in soap products, efforts at a solution have given rise to the study of soap substitutes and newer soap mixtures. The presentation of these newer products has led to a review of what genuinely constitutes the soap problem.

The overwhelming majority of people, who have healthy skin, find the average toilet soap a completely safe and effective cleanser. But a sizable group, principally among women, find that the use of soap leaves the skin too dry and its surface flaky or irritated. Until now, dermatologists have minimized these complaints and have regarded the group as finicky and the willing victims of cleansing cream sales-promotion activities.

A matter of more concern to the dermatologist is the role of soap in producing and maintaining dermatitis. It is generally accepted that the use of toilet soap occasionally results in dermatitis and much has been written relative to the cause of this dermatitis. Because of a relatively strong cation and weaker anion in their composition, soap solutions are invariably alkaline, and this alkalinity has been regarded as the fundamental cause for the adverse skin reaction in these cases. Using a solution of 1 per cent in distilled water, I have tested many toilet soaps and found them all to have a pH between 9 and 10. This is true for the so-called superfatted soap and for the laundry soap also. However, since this range of alkalinity is too feeble to act as an effective keratolytic during the momentary exposures required for ordinary cleansing of the skin, damage will occur only if the alkalinity is transmitted through the horny surface of the skin to the epithelial layer below. I have attempted to probe this thought by dialysis experiments with soap solutions. The results of these tests are given in Table 1.

Using both "gut" and collodion bag membranes and dialyzing 1 per cent solutions of soap against distilled water, tests on the

diffusates after one hour and also after eighteen hours of dialysis reveal that all toilet soaps fail to communicate the full strength of their alkalinity through the membrane but that laundry soaps have that tendency.

Since clinical experience points to a greater risk of dermatitis from laundry soap, one may continue to suspect, at least on the basis of these tests, that the alkalinity of these soap solutions plays a part in the production of the dermatitis. By the same token, however, we may believe that alkalinity does not enter as a factor in the production of dermatitis from toilet soap. I make these deductions from the tests with full knowledge that the keratin of the skin surface is not completely comparable as a membrane barrier to those employed in the tests. The point I wish to stress is that the risk of damage from the alkalinity of soap occurs only when that alkalinity is made available beneath the horny layer of the skin. Soap manufacturers who boast of the absence of "free alkali" in their toilet soaps should demonstrate by some such test as here recorded the degree of alkalinity liable to diffusion through the horny layer of the skin. I see no good reason for suspecting that a satisfactory laundry soap cannot also be achieved, a laundry soap whose diffusible "alkali" will not exceed that of toilet soap.

The other side of the picture of toilet soap dermatitis is the role that the fatty acids may play in its production. The literature records many cases of soap dermatitis due to sensitization to specific fatty acids in soaps. These soap allergies are in the same category as the disabilities arising from the perfumes in soaps and have been the chief background for the introduction of soap substitutes. Essentially, these substitutes have been of two varieties: wetting-agent compound products and hydrophylic oils—that is, oils miscible with water.

I am strongly opposed to the use of the former type of soap substitutes, on the grounds that wetting-agents are known to increase the permeability of the keratin surface of the skin. One need not dwell on the potential dangers from such a change. The use of this type of cleansing agent would increase the incidence of dermatitis venenata and contact allergies in the group who practice this form of skin cleansing.

History

Case (J 49406)

DR. ROBERT McGRATH: This patient was a 46-year-old divorced female who was admitted to the hospital with the chief complaint of a cough of three months' duration. The patient had resided formerly in California. About four months prior to admission, she began to lose weight, dropping gradually from a normal weight of 98 pounds to 82 pounds. This was accompanied by weakness, a hacking cough, and drenching night sweats. The cough had become productive of thick whitish sputum and was associated with pain in the left side of the chest. The temperature spiked to about 102 F. each afternoon. Except for typhoid fever in childhood, her past and family histories were negative. There had been no menstrual period for three months. There were no further suggestive symptoms.

Physical examination showed an undernourished, poorly developed white woman coughing continuously and appearing chronically ill. The temperature was 102 F., pulse rate 104, and respiratory rate 20 per minute. The tongue was coated. Blood pressure was 90/54 mm. of mercury. The heart rhythm was regular; there was a systolic murmur at the base of the heart. Over the left upper lobe of the lungs there was a slight impairment of resonance. The breasts were atrophic with small, firm, freely movable nodules of varying size in each breast. There were no skin or nipple changes. The deep reflexes were hyperactive, but the remainder of the physical and neurological examination was negative.

Laboratory Data.—Urinalysis was normal. The blood count showed a secondary anemia with 41 per cent hemoglobin, and 3,120,000 red blood cells per cu. mm. The white blood count was 84,850 per cu. mm. with a differential of 95 per cent neutrophils, 4 per cent lymphocytes, and 1 per cent monocytes. Several young neutrophils were noted and there was moderate anisocytosis. The blood Wassermann and Kahn tests were negative. The blood chemical studies were entirely within normal limits with the exception of the plasma cholesterol, which was 135 mg. per

cent. An x-ray examination of the chest was normal, except for a generalized accentuation of the pulmonic marking suggesting slight central thickening as well as pulmonary hypervascularity. The hypervascularity was a shade more discernible in the right upper lobe, where slight thickening of the upper septum also existed. A flat abdominal plate gave no evidence of any gross abnormalities but suggested a moderate enlargement of the spleen. A gastrointestinal x-ray revealed, after the patient's ingestion of a contrast meal, a moderate dilation of the upper esophagus with an extensive, multiple nodular intrusional defect fully 4 inches in length, extending from the fourth to the eighth dorsal vertebrae. The lumen of the esophagus was somewhat constricted and deviated to the right, but there was little obstruction to the contrast meal. Examination of the stomach was essentially negative except for displacement by an enlarged spleen. The lower margin of the spleen extended almost to the level of the iliac crest. The liver shadow was prominent. There was hypomotility with moderate stasis and distention of the terminal ileum. Numerous examinations of the sputum failed to reveal acid-fast bacteria. The sputum was never bloody.

During the patient's stay in the hospital her temperature was normal each morning but reached 101 F. to 102 F. each evening. The white blood count remained stationary at a high level with no change in the differential. She was discharged without treatment but went progressively downhill and was readmitted three months later when there was a further weight loss. The fever and cough had continued, and the physical examination was unchanged except for the development of a small subcutaneous nodule on the right side of the abdomen which was about the size of a walnut and dusky red in appearance. It was fluctuant, and necrotic material and pus were obtained on aspiration. The marked anemia and leukocytosis persisted, and the patient went steadily downhill. Shortly before death a palpable mass was noted in the posterior aspect of the right thigh. Death occurred four

water. As you have heard, the lower fatty acids are rather active sensitizers. Undoubtedly, soaps, through their essential detergent properties, remove some of the natural protectant oils of the skin. Dr. Sharlit suggests that damage occurs only from the alkalinity of the soap if transmitted through the horny surface of the skin to the lower epithelial layers. The suggested remedy is a soap preparation containing an excess of oil which would act as a protectant and prevent penetration of irritating properties of the soap and water.

You have heard that the sulfonated oils and wetting-agents, unless specially treated, defat the skin and in higher concentrations have a relatively high index of sensitization (probably owing to their excellent penetration). Doctors Quinby and Fiero have combined a sulfonated hydrogenated castor oil, a wetting-agent with petrolatum and water, and have found such a preparation relatively nonirritating, a satisfactory detergent, and yet psychologically agreeable to the patient. A 5 per cent solution of this preparation has a pH of 6 to 6.3. There can be little doubt that it sounds most reasonable to use cleansing preparations whose pH corresponds closely to that of the normal skin surface, but has it been definitely proved that the minor variations in the pH of average soap preparations are the chief cause of trouble? Incidentally, I believe Dr. Sharlit neglected to state the pH of his soap substitute. According to Pillsbury and Shaffer, the intact skin is able to withstand solutions of pH ranging from -2 (three times normal hydrochloric acid) to pH 12.6, while the response of abraded skin to alkaline solutions up to and including pH 12.6 is no worse than that of intact skin. As far as practical purposes are concerned, since preparations of an experimentally tested pH may, and probably do, have minor variations of pH under different conditions of ordinary usage, we must return to the points on which both clinicians and experimenters are agreed. The skin requires a protectant film of oil or fat. When the natural protectant film has been reduced or removed, the skin is liable to irritation from solutions whether their pH is that of the normal skin or is slightly above or slightly below normal, and it is reasonable to suppose that the depth of their penetration and the sensitizing properties of the detergent solutions play an important role. Since both presentations, in es-

sence, consist in giving us a substitute for ordinary soap, the questions of whether the penetrating effect of a soap irritant is most important, whether the sensitizing effect, perhaps without much penetration, is the thing that counts, or whether it is a combination of both remain relatively unimportant in this discussion. Probably one factor is important in one subject and a different one in the next. Both papers therefore emphasize the same point—namely, the necessity of replacing the natural oily protectant film of the skin as regularly as it is removed by washing. The great question must then be: Can this be done satisfactorily in the one operation? Frankly, I doubt it. If the only factor causing defatting or excessive drying of the skin were the use of the detergent, I believe it might be accomplished. But as I pointed out earlier, there are, in my opinion, many factors that bring this about. However, I do not mean to say that what Doctors Sharlit, Quinby, and Fiero propose is not a valuable step in the right direction. I heartily endorse what they have done and hope they will continue their efforts without being discouraged if they find that the additional use of a grease cream may prove to be a necessity to accomplish the desired purpose.

A word about the use of the emulsified sulfonated castor oil preparation as an ointment base. Undoubtedly, when wisely selected, it should prove to be of great value. For example: I believe that in treating the focus of infection in a case of dermatophytosis, penetration of the antiseptic is essential; the hydrophilic value of such a base should not be forgotten for use, among other things, in oozing and weeping eruptions; it should also make an excellent base to use on the scalp. However, one must remember that with the use of the new base the strength of the various ingredients must generally be much reduced, as 2 per cent salicylic acid will give the full effect of from 5 to 10 per cent in an ordinary ointment base. It is necessary, therefore, to use great caution in evaluating such a base, and none of us should jump to conclusions one way or the other without considerable clinical trial and mature consideration. I wish to congratulate both the contributors for their good work along lines that for a long time have particularly interested me and which cannot fail to be of general interest to both physicians and layman alike.

lymph nodes, are composed of cells similar to those in the primary tumor.

In passing, one should note that unusually high and sustained leukocytoses, although uncommon, are occasionally observed in cases of malignancy.

Pathologic Diagnoses

1. *Squamous cell carcinoma of the esophagus.*

2. Secondary carcinoma of the trachea, regional lymph nodes, and skin.
3. Purulent bronchitis.
4. Lobar pneumonia and abscess on the left side.

HERMAN O. MOSENTHAL, M.D., *Chairman*

NOTES ON SOME MILITARY SURGEONS THROUGH THE CENTURIES

Pedanius Dioscorides, a Greek, who flourished about A.D. 54 to A.D. 68, was army surgeon under Nero (A.D. 37-68)—Nero Claudius Caesar Augustus Germanicus, who was Roman Emperor in A.D. 54-68.

Guglielmo Saliceto, born at Piacenza, Italy (1210-May, 1277), preferred the knife to cautery.

Arnold von Villanova (about 1300), Heinrich von Pfolspeundt (mss. 1460), in his *Bundth-Artzeney* concerned with wounds of war, and Hieronymus Brunschwig, too, deal explicitly with gunshot wounds.

Giovanni Da Vigo (1460-1525) was surgeon to Pope Julius II ("Practica Copiosa in Arte Chirurjica," Rome, 1514); Hans von Gersdorff ("Feldtbuch der Wundartzney," Strassburg, 1517), and Andea Della Groce ("Officina chirurgica," Venice, 1596), who discusses cauterization of wounds in the battlefields, may be mentioned among military surgeons.

John of Ardenne (circa 1306-1309?), physician to John of Gaunt, was the earliest English surgeon, actually getting his training on the battlefields of France in the Hundred Years' War. A skillful operator, he obtained excellent results by cleansing wounds instead of using salves.

Aurelius Cornelius Celsus (circa 25 B.C.-A.D. 40?), a Roman literary gentleman and philosopher and author of "De Medicina" (1478, Florence), probably saw some battle wounds, although he was not a surgeon. He flourished during the reign of Tiberius Caesar (born November 16, 42 B.C.). He gave a special diet for ulcer of the stomach—no acid or acrid substances!

Ambrois   Par   (1510-1590), one of the greatest military surgeons of all time, became an army surgeon in 1537, at the age of 27.

Dominique-Jean Larrey (1766-1842), who was the greatest French military surgeon of the Napoleonic Era, surgeon-in-chief to the Grande Arm  e, and was himself three times wounded, participated in over sixty battles.

Claudius Galen (A.D. 130-200), founder of experimental physiology, treated Emperor Marcus Aurelius Caesar (A.D. 121-180), following his battles, for aggravated attacks of "indigestion," probably due to gastritis or gastroduodenal ulcer made worse by his participation in the wars of that time. Marcus Aurelius later died in Vienna (probably of gastric ulcer or carcinoma—per-

foration?). Galen began to practice in Rome in A.D. 164. ("On Prognostics," Chap. XI). Diocles (fourth century B.C.) of Carystus, son of the physician Archidamus, described accurately the symptomatology of ulcer of the stomach—and its relation to mental disturbances. And, he may have noted aggravated gastric disturbances due to participation in the wars of the time. (Quoted by C. Galen: *De Locis Affectis*, Liber III, Cap VI, "De Melancholia," p. 58 verso-p. 59, Paris, H. Stephanus, 1513.)

F. J. V. Broussais (1772-1838), pupil of Bichat, was surgeon of the Armies of France.

Finally, William Beaumont (1785-1853), author of the famous "Experiments and Observations" (1833), was an army surgeon, as well as a pioneer American physiologist. True military hospitals were founded at the Siege of Alora (1484) and at Baza (1489). It is interesting to note that first-aid treatment in the Roman Army is depicted on Trajan's Column. Fielding H. Garrison wrote "Notes on the History of Military Medicine," Association of Military Surgeons, 1922, Washington.

In about 1320 B.C. Moses led Israel out of Egypt—and there may have been aggravated stomach disturbances during this period among the refugees.

During the time of Homer (800-900 B.C.), and Alexander's (400 B.C.) victory over Persia, and the fall of Jerusalem, military surgeons must have been kept quite busy. This was, perhaps, equally true when Rome conquered Greece (150 B.C.), when Spain was vanquished and conquered by the Arabs (eighth century A.D.), and during Chaucer's time and the time of the One Hundred Years' War (fourteenth century A.D.).

Let us mention here Florence Nightingale (1820-1910), who did so much during the Crimean War (1854-1856), and Edith Cavell, who was cruelly executed (shot) by the Germans on October 12, 1915! Horace (65-68 B.C.), the Roman poet—Quintus Horatius Flaccus—suffered from eye trouble (rheumatic) and gastric disturbances, no doubt made worse by his participation in the Battle of Philippi (42 B.C.). Julius Caesar died in 44 B.C. Horace died suddenly, perhaps from coronary thrombosis or a perforated gastric lesion.—Hyman I. Goldstein, M.D., *J. Med. Soc. of Cape May County, N.J.*

months following the first admission to the hospital.

Discussion

DR. JAMES FLEXNER: This case presents several aspects.

If one considers it from the standpoint of the history alone, it would suggest a low-grade chronic infection. When one notes the physical and laboratory findings, however, a much larger variety of conditions must be considered. The possibilities of chronic infections, leukemias, malignancies, benign and malignant lymphomas must be suspected.

Among the infectious processes the likelihood of a tuberculous involvement is suggested by the history of coughing, low-grade fever, weakness, and night sweats, with marked weight loss. On the other hand, the x-ray of the chest, negative sputa, and the white blood count of 84,500 would make this diagnosis unlikely.

Opposed to the diagnosis of syphilis would be the negative Wassermann and Kahn reactions, the absence of history of all primary or secondary lesions and the absence of vascular and neurologic manifestations.

The patient's residence in California makes consideration of the diagnosis of tularemia imperative. Ulceroglandular and pneumonic types of the disease have been described. The x-ray findings of the chest do not fit the usual reported findings, and the late appearance of the skin lesions would be rather unusual.

Blastomycosis and actinomycosis must be considered. They could give both the skin manifestations and the mediastinal changes which have been described. It is more common for the skin manifestations to precede the visceral involvement, and when the viscera are involved, there is usually a more excessive febrile course.

In spite of the leukemoid picture presented by the very high total white blood count, I believe that the absence of abnormal cells precludes the diagnosis of chronic leukemia. Bone marrow studies, however, might have been helpful.

Under the discussion of neoplasm, one must consider the site of primary involvement. With primary involvement of the esophagus, the lesions, though frequently silent, should have given more marked symptoms with the extensive involvement which has been revealed by x-ray. It is also extremely rare for esophageal neoplasms to metastasize to the skin.

Primary carcinoma of the bronchus is frequently silent until obstruction causes atelectasis and metastases manifest themselves. The patient's persistent cough could be explained in this manner. It would also be possible for the mediastinal glands to become involved with the invasion of the esophageal wall. The marked leukocytosis could be associated with a neoplastic involvement.

Malignant lymphoma or Hodgkin's disease could readily explain all of the findings presented by this case. The white blood count in Hodgkin's disease has been reported to exceed 100,000, with a marked increase of neutrophils. The prolonged febrile course, with profuse sweating, the skin lesions, and infiltration of the esophagus might also be explained by this malady. The very rapid sedimentation rate, large spleen, and hepatomegaly are also frequent findings in Hodgkin's disease.

There have been reports in the literature of gastric invasion in Hodgkin's disease, but I do not recall any records of esophageal involvement. Examination of the aspirated material from the skin lesions should have settled this question.

In benign lymphomas, such as Boeck's sarcoid and Kaposi's sarcoma, the primary lesions usually occur in the skin; and in the case of sarcoid particularly, diffuse pulmonary and bony involvement is common.

Dr. Flexner's Diagnoses

1. Hodgkin's disease.
2. Neoplasm, primary site in the bronchus.
3. Possible tularemia.

Pathology

DR. MAURICE N. RICHTER: The principal lesion is in the esophagus. Here there is a neoplasm measuring 7 by 5 by 3 cm., involving the portion of the esophagus opposite the first and third dorsal vertebrae. The neoplasm caused partial obstruction of the esophagus with ulceration and also extended to the surrounding tissues and infiltrated the trachea. On the inner aspect of the trachea there was ulceration of the mucosa. The entire wall of the trachea at this point is infiltrated with carcinoma cells. At the base of the left lung there was a small abscess a little less than 2 cm. in diameter. No abscess was found on the other side.

The tumor is squamous cell carcinoma arising in the esophagus. The subcutaneous nodule in the right side of the abdomen is a metastasis. This, and the metastases in the regional

months later x-ray treatments were administered to her pelvic region for the purpose of sterilizing her.

A severe skin reaction followed the series of x-ray treatments administered to the breast and shoulder, although as the patient continued to return to the hospital it was apparent that her cancer was controlled as a result of such treatments. She later went to another hospital where a cordotomy was performed for the purpose of relieving a painful condition of the right arm which developed. Following the operation, however, the patient had a complete motor paralysis of the right arm.

The patient instituted a malpractice action against the hospital and eight physicians associated with its staff. Four of these eight physicians were never served with any papers in the case and

the action was never pressed against the hospital. Just before the trial of the case the plaintiff discontinued the action against all of the physicians except the one who had been in charge of the actual rendering of the x-ray treatments. Upon the trial of the case the plaintiff attempted to contend that the reaction which she had sustained following the x-ray treatments was indicative of malpractice on the part of the defendant physician. Actually, the proof showed upon the trial that the reaction which the plaintiff had sustained was inevitable as a result of the proper treatment of a very severe malignant condition and that she was fortunate to be alive at the time of the trial. At the conclusion of all the testimony of the case the Court directed judgment in favor of the defendant, thereby exonerating him from all charges of malpractice.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Surgeon's Responsibility for Acts of Anesthetist

IN A recently decided case in a nearby state, the Appellate Court passed upon the question of the extent to which a surgeon may be liable for the acts of an anesthetist, and in determining the matter, an interesting decision was handed down.*

The plaintiff engaged a certain Dr. W. to perform upon her a major operation. A spinal anesthesia was agreed upon and the surgeon engaged a Dr. M. to act as anesthetist. Preparatory to the operation, and, in fact, before Dr. W. entered the operating room, Dr. M. introduced a needle between the vertebrae and it broke off. At that point Dr. W. entered the operating room, obtained another needle, administered a spinal anesthesia himself, and proceeded with the abdominal operation. Some days later the patient underwent a second operation by Dr. W., during which, after considerable difficulty, the imbedded needle was removed. There was no doubt that the patient suffered severe physical consequences from the breaking of the needle and the operation for its removal.

The patient instituted a malpractice action against the two doctors, charging both of them with negligence in connection with the breaking of the needle and the treatment which followed. The case was tried before a jury and at the conclusion of plaintiff's evidence the Trial Court directed the jury to return a verdict in favor of both physicians.

An appeal was taken by the plaintiff, and the Court of Appeals, with respect to the case against Dr. M., the anesthetist, found that there had been sufficient evidence introduced to make out a prima facie case of negligence. Consequently, the case was sent back for a new trial as far as he was concerned. The Appellate Court, however, found that the circumstances did not establish a cause of action against the surgeon and directed that the judgment of dismissal in favor of Dr. W. should be affirmed. In so ruling the Court stated in part in the opinion:

* *Wiley vs. Wharton* 41 N.E. (2nd) 255.

"Directing attention now to the claim of liability against Dr. W. and the evidence offered in support of the charge, this Court is of the opinion that the judgment of the Trial Court in determining, as a matter of law, that the evidence did not establish, as to him, a prima facie case of negligence, was correct.

"In reaching this conclusion, we are mindful of authorities which hold that, when one physician, acting in concert with another in the performance of an operation, perpetrates an act of malpractice, the other may be held liable for the acts of the tort-feasor if he observes such tortious conduct and lets it continue without objection, or if he fails to observe and act upon that which, in the exercise of ordinary care and diligence under the circumstances, he should have observed and acted upon.

"We also have considered the doctrine of *respondent superior*, and conclude that a discussion of that doctrine would be entirely obiter under the circumstances of this case.

"Dr. W. and the plaintiff entered originally into a consensual contract. At the time the parties understood that Dr. W. was not to administer the anesthetic but was to perform the abdominal operation. Dr. W. suggested that Dr. M. be engaged. No objection was interposed by the plaintiff. The plaintiff accepted the services of Dr. M., and although Dr. W. actually engaged Dr. M., nevertheless there was created between the plaintiff and Dr. M. a separate contract by implication. Under the circumstances each doctor was engaged to perform his separate and distinct work, independent of the other.

"The record discloses no negligence by Dr. W. in his selection of Dr. M., nor does it reveal that the practice and custom in this or a similar community required the presence or assistance of Dr. W. in the operating room while the patient was being anesthetized; nor does it reveal any acts performed in concert with Dr. M. for which Dr. W. might be held liable for the negligence of Dr. M."

X-ray Treatment of Cancer

A MARRIED woman, 33 years of age, was referred to a hospital clinic by her family physician, who had diagnosed her condition of recurrent carcinoma of the right breast. At the hospital the patient gave a history of having first noticed a lump in the region affected some three years before, and during the intervening time the condition had been twice operated upon. It was learned that she was the mother of two children, 5 and 3 years of age, respectively, and that she had nursed both of these children. She

was examined and the diagnosis was confirmed, and she was referred by the attending physician in charge to the x-ray staff for the purpose of receiving certain x-ray treatments as outlined by the attending physician. Under the supervision of two physicians connected with the x-ray department, the patient received aggressive x-ray treatments over a period of several weeks, which were directed to the region of the right breast and shoulder. These treatments were administered on nineteen separate days, and several

The speaker was the Rev. Earle Anabel, assistant pastor of St. Thomas Aquinas Church, who discussed the "Philosophy of Humor."

Agfa Ansco representatives showed films to demonstrate the latest advancement in colored movies.

Dr. Frank G. Moore, of Endicott, was elected secretary. Other officers are: assistant secretary, Dr. J. C. Zillhardt; treasurer, Dr. Ben L. Matthews; assistant treasurer, Dr. Leonard J. Flanagan; chairman of the economics committee, Dr. Charles J. Marshall; chairman of the legal committee, Dr. Frank M. Dyer; public relations director, Dr. Charles M. Allaben; public health, Dr. Ralph M. Vincent; milk commission, Dr. P. H. Shaw; library chairman, Dr. S. B. Blakely; membership, Dr. Ralph J. McMahon.

Dr. H. I. Johnson and Dr. George C. Vogt were named delegates to the 1943 annual meeting of the State Society.

The board of censors will include: Dr. John J. Cunningham, of Binghamton; Dr. William H. Hobbs, of Binghamton; Dr. Silas D. Molyneaux, of Binghamton; Dr. Frank G. Moore, of Endicott; and Dr. George C. Vogt, of Binghamton; delegates to the State Society will be: Dr. Harry I. Johnston, of Binghamton; and Dr. George C. Vogt, of Binghamton; alternate delegates: Dr. Samuel M. Allerton, of Binghamton; and Dr. Frank M. Dyer, of Binghamton.

Chautauqua County

The annual meeting of the county society was held on December 16, at the White Inn at Fredonia, at which time the following officers were elected: president, Dr. C. Otto Lindbeck, of Jamestown; vice-president, Dr. Oscar T. Barber, of Fredonia; secretary, Dr. Edgar Bieber; and treasurer, Dr. F. J. Pfisterer, both of Dunkirk.

Delegates to the State Society are Dr. Edgar Bieber and Dr. W. G. Hayward, of Jamestown.

At the scientific session following the election of officers a paper was given by Dr. Wendell R. Ames, Health Commissioner of Cattaraugus County, on "Factors in the Development of Typhoid Carrier Stage." As an added attraction a sound film on otitis media was presented.

Chemung County

Dr. Florence S. Hassett was elected president of the Chemung County Medical Society at a meeting on December 9 at the Arnot-Ogden Hospital.

Others named were vice-president, Dr. R. Scott Howland; secretary, Dr. John H. Burke, Jr.; treasurer, Dr. M. Frederick Butler.

Dr. Howland was substituted in the nomination for Dr. S. L. Larson, who was called into Army service.*

Chenango County

The 138th annual meeting of the Chenango County Medical Society was held at the Scintilla restaurant in Sidney on December 9. A steak dinner was served to about forty members and guests.

At the business session the following officers were chosen:

President, Dr. William P. Elliott, of New Berlin; vice-president, Dr. E. F. Gibson, of Norwich;

secretary and treasurer, Dr. John H. Stewart, of Norwich; member of board of censors, Dr. John A. Hollis, of Norwich.

Dr. A. K. Benedict of Sherburne was named as a delegate to the State Society, with Dr. J. M. Crumb, of South Otselic, as alternate.

Committee chairmen for the Society appointed for the coming year are: legislation, Dr. J. M. Crumb; economics, Dr. Edward Danforth, of Sidney; public health and education, Dr. E. F. Gibson; maternal welfare, Dr. C. D. Meacham; and committee on tuberculosis, Dr. A. K. Benedict, of Sherburne.

Dr. Elliott presided at the meeting in the absence of Dr. Ben Dodge, of Bainbridge, who is now in military service.

A resolution offered by Henry M. Champion, president of the Chenango County Taxpayers Association, advocating the closing of Brookside Crest at Sherburne was read at the meeting. The communication was placed on the table with no action being taken.

Following the meeting the physicians were taken on a trip of inspection of the Scintilla plant.*

Clinton County

Officers of the Medical Society of the County of Clinton for 1943 are: president, Dr. Sidney Mitchell; vice-president, Dr. Phillip B. Barton; secretary-treasurer, Dr. T. A. Rogers; and censors: Drs. L. H. Caswell, C. D. Silver, and Aaron Davis.

. . .

The committee minora of the county society held a business meeting on December 16, following a dinner which was served at the American Legion Home.

Physicians named to attend the dispensary at the Clinton County Home during the coming year were: Dr. E. W. Sartwell, of Peru; Dr. Aaron Davis, of Mooers; Dr. A. Z. Speare, of Altona; and Dr. Phillip Barton, of Amsterdam.*

Erie County

The Buffalo War Council has ratified the appointment of the following doctors, by Dr. G. Nelson Russell, chairman, to the Health Preparedness Committee: Dr. Harold F. R. Brown, chairman of Emergency Medical Division, War Council; Dr. Harvey Hoffman, Erie County Medical Society; Dr. George Slotkin, Buffalo Academy of Medicine; Dr. Leslie Murray, Eighth District Dental Society; Dr. William T. Clark, Edward J. Meyer Memorial Hospital superintendent; Dr. Archibald S. Dean, state district health officer; Dr. Stockton Kimball, Council of Social Agencies, Health Division; Dr. Roy L. Scott, Buffalo Chapter, American Red Cross; Dr. Albert H. Garvin, Buffalo Tuberculosis Association.*

. . .

A plea that doctors "strive to maintain the decent independence of our profession" during the period of social readjustment following the war was sounded on December 23 by Dr. Harvey P. Hoffman in his final address as president of the Medical Society of the County of Erie.

Dr. Hoffman addressed the society in Hotel Statler at the annual meeting, which unani-

Medals of the Army Medical Department

IN A monograph recently published by the American Numismatic Society, Hume describes a series of twenty-four medals, struck in gold, silver, and bronze, that have been awarded in recognition of scientific or academic attainment by members of the United States Army Medical Department. Some of these medals were awarded for work of great importance to our country; they serve also to reflect the quality of the army medical educational system. The Army Medical School, the oldest army service school, possesses the oldest medal in the Army awarded for academic standing. At the time of the War Between the States, Surg. Gen. William A. Hammond proposed the establishment of such an institution, but it did not then materialize. Surg. Gen. George M. Sternberg, with the support of a later secretary of war, Daniel S. Lamont, established the Army Medical School in 1893. The Army School of Nursing was established in 1918, the Medical Field Service School in 1920, the Army Dental School in 1921, and the Army Veterinary School in 1922. All these schools have medals created as awards for academic attainment. The medals were established by private gift, although accepted by the Army Medical Department and given official recognition. The school of Aviation Medicine also was established in 1922. Hume has reproduced the design of these medals and given brief biographies of some of the recipients.

A second group of medals reviewed are those that have been awarded to certain distinguished members of the Army Medical Department. The Gorgas Medal was presented by the American Medical Association at its annual meeting in 1914 to Surg. Gen. William C. Gorgas, "whose genius made possible the construction of the Isthmian Canal." The Congressional Walter Reed Medal honoring the chairman of the Army Commission whose experiments proved that mos-

quitoes transmit yellow fever was struck some thirty years after the commission did its work and long after Major Walter Reed had died. Hume reviews again those famous experiments. Another Walter Reed Medal was created by the American Society of Tropical Medicine in 1934, to be awarded to individuals or institutions in recognition of meritorious achievement in tropical medicine. The Bailey K. Ashford Medal was established by Eli Lilly & Co. in 1940 and accepted by the American Society of Tropical Medicine, which was given the right to select the winners. The Wellcome Medal, established by the late Sir Henry Wellcome of London, an American by birth, has been awarded by the Association of Military Surgeons of the United States annually since 1916 for the best research, discovery, invention, essay, or other acts or deeds which the association considers helpful in the attainment of its objects and relating to any phase of medical military affairs and disease control associated with the Army, Navy, Militia, and Public Health Service.

There have been numerous other awards. The Sedgwick Medal was awarded to Brig. Gen. Frederick F. Russell, who was largely responsible for the introduction and use of typhoid vaccine in the Army. Surgeon General Sternberg was awarded several medals, including one by the American Medical Association; John Shaw Billings, Deputy Surgeon General of the Army and the father of the Army Medical Library, received several awards. This monograph is limited, however, to medals honoring medical officers rather than to medals won by individual medical officers.

The award of medals is a time-honored method of recognizing merit. Hume's monograph will aid collectors and bring home to many others the scientific accomplishments of United States Army medical officers.—*J.A.M.A.*, December 26, 1942.

County News

Albany County

Officers elected on December 9 for 1943 are: president, Dr. Morgan O. Barrett; vice-president, Dr. John B. Horner; secretary, Dr. Homer L. Nelms; treasurer, Dr. Frances E. Vosburgh; historian, Dr. Emerson C. Kelly; censors: Dr. John J. Phelan, chairman, Dr. James A. Hogan, Dr. Donald D. Prentice, Dr. Benno J. Troidle, Dr. Arthur J. Wallingford; delegates: Dr. Otto A. Faust, Dr. James S. Lyons, Dr. Homer L. Nelms; alternate delegates: Dr. Jacob L. Lochner, Jr., Dr. I. J. Murnane, and Dr. Clarence A. Traver. All the officers are residents of Albany.

Bronx County

At a meeting of the North Bronx Medical Society on January 7, at Elmsere Hall, the following program was given: "Heart Disease Complicating Pregnancy," by Dr. Harry B. Biscow; discussion by Dr. Hyman J. Epstein; "Throm-

boangitis Obliterans in a Man Past Seventy," by Dr. Gamliel Saland; discussion by Dr. Isidor Mufson; "Persistent Ventricular Tachycardia During Coronary Thrombosis with Recovery," by Dr. Benjamin Archer; discussion by Dr. Solomon Krell; "Gall-bladder Disease Simulating Psychoneurosis," by Dr. Samuel Weiskopf; discussion by Dr. Benjamin Sherwin; "Orchiectomy for Carcinoma of Prostate," by Dr. Isidor Palais; discussion by Dr. Paul W. Aschner.

General discussion was held at the close of the program.

Broome County

Dr. Elton R. Dickson was re-elected president of the Broome County Medical Society at their annual dinner meeting.

Wives of members of the society now serving in the armed services were guests. Other members of the society's auxiliary also participated.

ports and discussion of current war conditions in medical practice.*

New York County

At the last 1942 meeting of the county society, on December 28, Major General Basilio J. Valdes, Chief of Staff of the Philippine Army, described "War in the Philippines from a Surgeon's Viewpoint."

An award of Citation of Merit was made to Dr. William B. Rawls by Col. Samuel Kopetzky, Medical Director of Selective Service, New York Area.

The following New Yorkers received awards for scientific exhibits at the American Congress of Physical Therapy: the silver medal to Drs. Karl Harpuder and Irwin D. Stein, of Montefiore Hospital, for photographs of minute blood vessels; the bronze medal to Dr. Kristian G. Hansson and Miss Florence Liljander, of the Hospital for Special Surgery, for exercises for low-back strain; honorable mention to Dr. Joseph Kovacs, of the New York Post-Graduate Medical School and Hospital, for diagnosis and treatment of leg ulcers.—*J. Med. Soc. Co.*

We should like to quote this editorial entitled "The Ramirez Administration," from the *Journal of the Medical Society of the County of New York*, December 26:

Probably no one ever assumed the presidency of the Medical Society of the County of New York under more trying circumstances than Dr. Maximilian A. Ramirez. Our entry into the war deposited many new duties and problems on the doorstep of organized medicine. Its multifarious peacetime activities had also to be continued. At the same time there was a continuous loss of experienced committee heads and members to the armed forces.

Despite these difficulties, Dr. Ramirez and his co-workers achieved greatly. The Committee on Medical Preparedness helped to mobilize the profession both for military service and for civilian Emergency Medical Care. Problems arising out of the rationing of tires and gasoline were ironed out with the proper authorities as they arose.

In spite of the pressure of wartime tasks, the Ramirez administration not only continued but expanded the county society's normal activities. One of its outstanding achievements was the organization of the Blood and Plasma Exchange Bank. Conceived during Dr. Alfred M. Hellman's presidency, the plan was completed and put into operation this year, with already manifest improvement in the supply of blood and plasma to the needy sick. Its ultimate benefits promise to extend far beyond the boundaries of New York County.

In the course of the year, a number of medical service plans were studied and action taken on them. Community Medical Care, Inc., was not approved; the "B" plan of the Group Health Cooperative, Inc., was. Active support was given to the Medical Expense Fund of New York.

In recognition of the need for more effective public contacts, the Radio Committee was reorganized and its activities broadened. Every effort was made to further the just aspirations of our women physicians. The *Journal* was launched in its present form.

The society's relations to municipal activities in the health and Hospitals Departments. A satisfactory understanding was reached with the Police Department regarding the parking of doctors' cars and the Commissioner of Licenses was persuaded to rescind the specification of a one-dollar fee for the physical examination of applicants for barbers' licenses.

No review of Dr. Ramirez' administration would be complete without reference to the exceptional quality of the programs for the stated meetings throughout his tenure of office. Unprecedented attendance records bear witness to the unflinching timeliness and interest of the programs he arranged.

Niagara County

Friends have received word that Dr. James S. Dawson, former Perry physician, is now practicing medicine in Wilson, N. Y. Dr. Dawson has been in Toronto and Little Current, Canada, for the past few years. In Wilson he has taken over the practice of a physician now in the service.

Onondaga County

Dr. James H. Bennett has been appointed substitute health officer for the Village of Baldwinsville.

Dr. Bennett was appointed to take over the duties of Dr. Justin W. Mignault, who was recently granted a leave of absence by the village when he joined the nation's service with the rank of assistant surgeon under the U. S. Maritime Commission.*

Orange County

Dr. Earl R. Van Amburg, of Pine Bush, was elected president, Dr. Walter I. Neller, of Middletown, vice-president, and Dr. Earl Waterbury, of Newburgh, was re-elected secretary and treasurer at the annual meeting of the Orange County Medical Society.

Forty-nine of the society's 170 members now are in the Armed Forces, it was disclosed.*

Rockland County

The Medical Society of the County of Rockland has elected the following officers for 1943: president, Dr. Marjorie R. Hopper, of Nyack; vice-president, Dr. Harold S. Heller, of Spring Valley; treasurer, Dr. Dean Miltimore, of Nyack; secretary, Dr. A. N. Selman, of Spring Valley.

Dr. Hopper is the first woman to be elected president of the Rockland County Medical Society. She is the health officer of the town of Clarkstown, physician for the Nyack public schools and the Upper Nyack public schools, and is a staff member of the Nyack Hospital, where she is an associate in obstetrics.

She was graduated from Smith College and Cornell Medical School and served her internship at the New York Infirmary for Women and Children. Besides taking care of her private practice she keeps house and has two children. She is the wife of Ivin Sickles, an artist.*

Schenectady County

The first mercy emblem of the Medical and Surgical Relief committee in Schenectady County has been presented to Dr. William F. Nealon, president of the county society, by Mrs. William M. Mallia, chairman of public relations and acting chairman of the Medical and Surgical Relief drive; Mrs. Charles F. Rourke, president of the woman's auxiliary of the county medical society; and Dr. Joseph Peter Houget, of New York, national medical director of the Medical and Surgical Relief Committee.

An emergency medical field service set was presented to Dr. James M. Blake, chief of the Schenectady emergency medical service, by Mrs. Burke and Mrs. Mallia, at Glenridge Sanitarium. Dr. Houget also attended the ceremony.*

Schuyler County

County society officers elected for 1943 at the annual meeting are: president, Dr. John W.

mously elected Dr. Harold F. R. Brown, first vice-president, to succeed Dr. Hoffman in 1943.

In reviewing the contributions of the society and individual members to the war effort, Dr. Hoffman reported that 302 Erie County physicians, of whom 198 are society members, already have gone into armed service.

Other officers chosen besides Dr. Brown are: first vice-president, Dr. John D. Naples; second vice-president, Dr. Patrick H. J. Buckley; secretary, Dr. Louise W. Beamis-Hood; treasurer, Dr. Ralph M. DeGraff; board of censors: Dr. Elmer T. McGroder, Dr. Francis E. Fronczak, Dr. Charles W. Bethune, Dr. Eugene M. Sullivan, and Dr. John C. Brady; delegates to the State Society: Dr. Alfred H. Noehren, Dr. Joseph C. O'Gorman, Dr. Brady, and Dr. Thurber LeWin; alternates: Dr. John T. Donovan, Dr. Norman C. Bender, Dr. Harold B. Johnson, and Dr. Mary T. Kazmierczak; chairmen of standing committees: Dr. Edmund A. Mackey, legislation; Dr. John W. Kohl, public health; Dr. Porter A. Steele, economics; and Dr. Arthur F. Glaeser, membership.*

Franklin County

Officers elected recently to head the medical society of Franklin County for 1943 include:

President, Dr. Francis B. Trudeau, of Saranac Lake; vice-president, Dr. Bruce T. Smith, of Fort Covington; secretary-vice-president, Dr. Philip Gorman, of Fort Covington; second treasurer, Dr. Daisy Van Dyke, of Malone; censor (three-year term), Dr. Philip Gorman; state delegate, Dr. C. C. Trembley, of Saranac Lake; alternate delegate, Dr. J. E. White, of Malone; and legislative committee, Dr. C. C. Trembley, chairman, Dr. J. W. Kissane, of Malone, and Dr. E. M. Austin, of Tupper Lake.

Genesee County

Dr. Ward B. Manchester, of Batavia, was elected president of the Genesee County Medical Society, succeeding Dr. Raymond L. Warn of Oakfield, at a meeting of the society held at the Batavia Club. Dr. Irwin A. Cole, of Batavia, was named vice-president, and Dr. Peter J. Di Natale was renamed secretary and treasurer.

Herkimer County

Dr. Byron G. Shults was re-elected president of the county society at the 136th annual meeting on December 8. Dr. Shults named the following executive committee: Dr. F. C. Sabin, of Little Falls; Dr. F. H. Moore and Dr. A. L. Fagan, of Herkimer; Dr. F. B. Conterman, of Ilion; and Dr. A. B. Santry, of Little Falls.

Other officers elected were: vice-president, Dr. N. D. Lill, of Dolgeville; second vice-president, Dr. D. F. Aloisio, of Herkimer; third vice-president, Dr. F. M. Neuendorfer, of Mohawk; secretary, Dr. Sabin; treasurer, Dr. Fagan; librarian, Dr. G. S. Eveleth, of Little Falls; censors: Dr. Moore, Dr. Sabin, Dr. Harold F. Buckbee, of Dolgeville, Dr. Harry J. Sheffield, of Frankfort, and Dr. C. C. Whittemore, of Ilion.

Dr. T. Wood Clarke, of Utica, historian, spoke on "Fairfield Medical School," recalling many incidents which occurred on the campus of a once prosperous educational institution, abandoned since the turn of the century.

Kings County

The Associated Physicians of Long Island will hold their annual meeting on January 30.

The scientific and business session will be held at the Methodist Hospital, where it is planned to have clinics in the morning. After luncheon there will be an inspection of the New Buckley Pavilion. The scientific session will take place at 3:00 p.m. Several short papers on various topics will be presented, followed by discussion.

At the business meeting, after the afternoon program, the annual election of officers will take place.

The annual dinner will be held at 6:30 p.m. at the Montauk Club. Members are reminded to reserve the date.—*Bull. Med. Soc. Kings Co.*

The Stated Meeting of the county society was held on Tuesday evening, December 15, at 8:45 p.m. in the McNaughton Auditorium.

The scientific program and speakers included: "Management of the Gynecological Cancer Patient," by William P. Healy, M.D., F.A.C.S., F.A.C.R., of New York City; and "Chronicity—A Mortality Factor in Gall Bladder Surgery" (illustrated by lantern slides), by Chas. Gordon Heyd, M.D., F.A.C.S., of New York City.

The acquisition by the society of a long needed public address system was made possible by members of the staff of the Jewish Hospital at the instigation of Dr. Abraham D. Segal.—*Bull. Med. Soc. Kings Co.*

Madison County

The following members were elected to office in the Madison County Medical Society for 1943:

President, J. W. Thro, M.D., of Hamilton; vice-president, A. E. Broga, M.D., of Oneida; secretary, Felix Ottaviano, M.D., of Oneida; treasurer, J. D. Boyd, M.D., of Chittenango.

The Society has had four Post-graduate Lectures. They have been well presented and very well received. Attendance has been fair, considering the number of physicians left in the county and the work that they have to do at this time.

We are happy to hear that Lee S. Preston, secretary of the society for many years, has been appointed to the office of Field Director, Division of Health Preparedness Committees, in Albany.—*Felix Ottaviano, M.D., Secretary.*

Montgomery County

Dr. Nicholas T. Lombardi, of Amsterdam, was elected president of the county society at the annual meeting held on December 15 at the Elks Club. Other officers named were: vice-president, Dr. Alton J. Spencer, of Canajoharie; secretary, Dr. Peter J. Lucas, of Amsterdam; treasurer, Dr. Melvin T. Woodhead, of Amsterdam.

Dr. Lombardi succeeds the late Dr. James M. Bernhard, and the new secretary is successor to Dr. Roger Conant, now with the Army Medical Corps.

There were no speakers, the session following a dinner being devoted to the reading of annual re-

bald, of Bedford Hills, retains the chairmanship of the medical economics committee; Dr. Gilbert Daldorf, of Grasslands Hospital, will again serve as chairman of the scientific committee.

Dr. Morton Ryder, of Rye, has accepted the chairmanship of the hospital committee; Dr. Harris W. Campbell of White Plains, of the membership committee; Dr. Isadore Zadek, of Mount Vernon, of the workmen's compensation committee, and Dr. Erich H. Restin, of Mount Vernon, will again act as chairman of the medical preparedness committee, a post which he has held since the beginning of the emergency.

In addition, Dr. Adie has announced the appointment of chairmen of special committees, as follows: Dr. James Denton, of New Rochelle, will continue as chairman of the special committee on cancer; Dr. William G. Childress, of Grasslands Hospital, will again serve as chairman of the special tuberculosis committee; and Dr. Alfred C. Emmel, of Mount Vernon, continues as chairman of the special maternal welfare commission.

Dr. Elton G. Littell, of Yonkers, has been appointed chairman of the special committee on the school health program; Dr. H. H. Stevens, of Yonkers, has been appointed chairman of the special committee on medical-pharmaceutical relations; and Dr. Clarence O. Cheney, of the New

York Hospital, Westchester Division in White Plains, will resume the chairmanship of the special committee on mental health.*

* * *

Delegates to the State Society also elected recently are: Dr. Arthur F. Heyl, of New Rochelle; Dr. Erich H. Restin, of Mount Vernon; Dr. Ralph T. B. Todd, of Tarrytown; Dr. Laurence D. Redway, of Ossining; and Dr. Andrew A. Eggston, of Mount Vernon; and alternate delegates: Dr. C. J. F. Parsons, of Dobbs Ferry; Dr. Ashley B. Morrill, of Bronxville; Dr. Henry J. Vier, of White Plains; Dr. Robert W. Helm, of Ossining; and Dr. Robert B. Archibald, of Bedford Hills.

Wyoming County

Newly elected officers of the Medical Society of the County of Wyoming are: president, Dr. G. A. McQuilkin, Varysburg; vice-president, Dr. G. S. Baker, of Castile; secretary-treasurer, Dr. G. W. Nairn, of Warsaw; delegate, Dr. H. S. Martin, of Warsaw; alternate, Dr. G. S. Baker, of Castile; censors, Dr. Mary T. Greene, of Castile; Dr. L. H. Humphrey, of Silver Springs; Dr. G. A. McQuilkin, of Varysburg; and tuberculosis committee, Dr. L. H. Humphrey, chairman.

SCIENTISTS TO ADVISE NBC

Formation of a committee of three scientists to study network broadcasting from the standpoint of morale and public health was announced recently by Niles Trammell, president of the National Broadcasting Company. The committee's members will act as permanent consultants to NBC and make recommendations on how the network may better its efforts to promote national welfare and aid the war.

Members of the committee, whose work will be supervised by Dr. James Rowland Angell, public service counselor to NBC, are Dr. Morris Fishbein, who will serve as chairman; Dr. Henry R. Viets, Boston neurologist and lecturer at the Harvard Medical School; and Dr. Winfred Overholser, professor of psychiatry at the School of Medicine of George Washington University.

Burton, of Mecklenburg; vice-president, Dr. W. Merscher, of Watkins Glen; secretary-treasurer, Dr. Oakley A. Allen, of Watkins Glen; delegate to the State Society, Dr. C. W. Schmidt, of Burdett; alternate, Dr. William C. Stewart, of Watkins Glen; censors, all members.

Appointed to committees are the following: medical preparedness and defense, Drs. J. W. Burton, W. C. Stewart, and O. A. Allen; compensation secretary, Dr. Allen; arbitration of bills, Dr. A. H. Jackson, of Watkins Glen; hospital committee, Drs. Schmidt and Allen; maternal welfare, Dr. P. F. Willwerth, of Montour Falls; deaf and hard of hearing, Dr. Jackson; public health, medical education, tuberculosis, and schools, Dr. Allen; public relations, Dr. Willwerth; and legislative, Dr. Burton.

Seneca County

Seneca County Medical Society officers elected for 1943 at the annual meeting on October 8 are: president, Dr. Roy E. Wallace, of Seneca Falls; vice-president, Dr. W. M. Pamphilon, of Willard; censors: Drs. R. F. Gibbs, of Seneca Falls; E. P. McWayne, of Fayette; and F. W. Lester, of Seneca Falls; and secretary-treasurer, Dr. Lester.

Committees appointed for the year include: comitia minora: Drs. Wallace, Pamphilon, Lester, Gibbs, and McWayne; procurement and assignment committee: Dr. Pamphilon, Dr. J. G. Gordon, of Ovid, and Dr. Wallace; legislative committee: Dr. Lester and Dr. A. F. Baldwin, of Waterloo; public relations: Dr. E. M. Wellbery, of Waterloo, and Dr. Gibbs; compensation committee: Dr. Baldwin, and Dr. A. Letellier, of Seneca Falls; economics committee: Drs. Gibbs and Wallace; public health committee: Dr. G. M. Brandt, of Seneca Falls, Dr. S. B. Folts, of Lodi, and Dr. Lester.

Tioga County

The entire slate of officers of the county society was re-elected at the annual dinner meeting held on December 9 at the Green Lantern Inn, when Dr. Hugh S. Gregory, superintendent of the Binghamton State Hospital, was the principal speaker.

Dr. J. B. Schamel, of Waverly, will serve as president for another year. His associate officers are as follows: vice-president, Dr. Hiram L. Knapp, Jr., of Newark Valley; secretary-treasurer, Dr. Ivan N. Peterson, of Owego; delegate to the State Society, Dr. Corbett S. Johnson, of Spencer; alternate, Dr. Fred K. Shaw, of Waverly; censors: Dr. F. A. Carpenter and Dr. F. H. Spencer, of Waverly, and Dr. John Jakes, of Candor.

Introduced by Dr. A. J. Capron, of this village, Dr. Gregory delivered a most interesting and informative address, dealing principally with the activities at the State Hospital.

The annual meeting was preceded by a dinner served at 6:30 o'clock, and after the business session an hour of relaxation and general sociability was enjoyed.*

Tompkins County

The following officers were elected at the annual meeting of the Tompkins County Medical Society, held in the Ithaca Hotel on December 16: president, Dr. J. N. Frost; vice-president,

Dr. R. H. Broad; secretary-treasurer, Dr. W. Wilson; censors: Dr. R. Douglass, Dr. L. P. Larkin, Dr. D. Robb, Dr. L. H. Speno, and Dr. H. J. Wilson, all of Ithaca; delegate to the State Society will be Dr. L. P. Larkin, who holds the office for the second year.

Dr. Ernest J. Simmons, associate professor of Slavic languages and literatures at Cornell University, addressed the society on Russia's international relations.*

Ulster County

The following item was clipped from the *Saugerties Post*:

"Dr. Alfred Berger has opened an office in Tannersville. A graduate of the University of Vienna in 1919, Dr. Berger spent two years in England before arriving in the United States with his wife in 1940. He holds a New York State medical license. While vacationing in a nearby Catskill resort he learned of the vacancy in Tannersville and decided to open an office for practice there."

Warren County

Officers elected at a meeting of the county society include: president, Dr. Burke Diefendorf, of Glens Falls; vice-president, Dr. James A. Glenn, of North Creek; secretary-treasurer, Dr. Morris Maslon, of Glens Falls; censors: Drs. W. W. Bowen, Dwight Sawyer, and Floyd Palmer, all of Glens Falls.

Washington County

Committee members appointed at the annual meeting of the county society whose names were not included in the list of officers published in the December 15 issue are: committee on workmen's compensation, Dr. W. S. Bennett, of Granville; committee on preparedness: Drs. E. V. Farrell, of Whitehall; V. K. Irvine, of Granville; R. E. Borrowman, of Ft. Edward; and D. M. Vickers of Cambridge.

Wayne County

Dr. Ralph Sheldon, of Lyons, was elected president of the Wayne County Medical Society for 1943 at its annual meeting held on December 9 in Lyons. He succeeds Dr. James L. Davis, of Newark, who was president the past two years and secretary-treasurer the previous seven years.

Other officials elected are: first vice-president, Dr. D. F. Johnson, of Newark; second vice-president, Dr. George W. Pasco, of Wolcott; secretary-treasurer, Dr. Thomas Hobbie, of Sodus (re-elected).

Annual reports were read and the doctors enjoyed a color movie showing the latest wartime plastic surgery work in England.*

Westchester County

Dr. George C. Adie, of New Rochelle, recently re-elected president of the Westchester County Medical Society, has announced the selection of committee chairmen for the coming year.

The public health committee will serve under the chairmanship of Dr. John B. Abouse, of Yonkers; Dr. Waring Willis, of Bronxville, will be chairman of the legislative committee; Dr. E. Leslie Burwell, of New Rochelle, chairman of the public relations committee; Dr. Robert B. Archi-

Virtually all the buildings will be one-story farm structures and must be completed by April 15.

The total cost of the project will be approximately \$4,167,341, which includes \$1,700,000 for materials to be furnished by the government. Already several carloads of lumber have been delivered to the site.

Col. A. J. Canning, formerly of Hawaii, arrived several weeks ago to be commanding officer at the new hospital, the largest of its kind in the area.*

With payment this year of the last note for \$4,000, Dansville General Hospital is now free of debt, according to the report of Mrs. A. E. Maloney, treasurer, submitted at the annual hospital meeting on December 2.

Announcement was made that because of increased operating costs involving nurses, labor, and food purchases, rates have been increased about one dollar daily, but in consideration of a \$3,000 annual appropriation from the Village of Dansville, a 5 per cent discount is available to residents of the village.*

Newsy Notes

Kings County, Beekman, and Bellevue hospitals were among the New York institutions that gave Christmas parties for children this year.

The usual Kings County children's Christmas party was held December 19, with playlets and presents and ice cream and cake—and Santa Claus. The latter was played by one of the members of the staff.

Excerpts from "Doodle Dandy of the U. S. A.," a musical play, were presented by Junior Programs, Inc., for the entertainment of nearly 150 young patients in the Psychiatric Auditorium at Bellevue Hospital.

The dancing and antics of Harold Steen, who played Doodle Dandy, had the children in high glee.

A Christmas festival with Chinese overtones eradicated the hospital atmosphere from the first floor of Beekman Hospital. Behind a huge Christmas fireplace, constructed in the main lobby, were toys and dolls for 300 children—or was it "thousands and thousands," as it seemed to Miss Dorothy Stickney, of "Life With Father," in the role of Mrs. Santa Claus, who helped dispense the toys?

Santa Claus himself, impersonated by Dr. Carl Smith, of the hospital staff, needed all the assistance he could get from former Governor Alfred E. Smith, a member of the board of directors; Howard Lindsay, of "Life With Father," and Howard Cullman, president of the hospital.

The Chinese atmosphere was supplied by two children from Boyer Street, Fannie and William Chin, who participated in a Christmas tableau with Miss Stickney and Santa Claus. In a playful compliment to "Life With Father," in which all the children of the cast have red hair, the two Chinese children were fixed up with red wigs. Theoretically, they were to help Mrs. Santa Claus with her chores, but the whole party took more pleasure in watching William teach Miss Stickney to say "Merry Christmas" in Chinese.*

Westchester Medical Bulletin. A preface by the editors follows:

"The editors consider it a distinct privilege to publish this article, which they believe constitutes one of the most reasonable and persuasive statements of the case for "group practice" yet offered to a medical audience.

"Dr. Mackenzie's practical experience and the widely known accomplishments of the Bassett Hospital in Cooperstown offer such tangible support for his argument that his proposals cannot be dismissed as mere theory. Nor can his suggestions as to the future of medical practice be lightly dismissed as pure speculation. It would be regrettable in our opinion if this discussion were to be concluded with this publication."*

The outpatient department laboratory of St. Luke's Hospital will benefit by the voluntary services of five Sarah Lawrence College girls, trained in the laboratory sciences, who will assist the hospital technicians. All of the volunteer aides have had at least two years of intensive study in biology, bacteriology, chemistry, physics, or a combination of them.

Dr. Homer W. Smith, professor of physiology at New York University College of Medicine and director of physiological laboratories there, will deliver the 1943 William Henry Welch lectures at Mount Sinai Hospital. The topic will be "The Physiology of the Kidney."

Sr. Don Manuel Prado, President of Peru, has accepted the honorary presidency of the International and Spanish-Speaking Association of Physicians.

The item quoted below appeared under "New York City Hospital News" in the *New York Civil Service Leader* for December 15:

"At Kings County hospital they are proud as anything over the advance guard that has just left for Ft. Blanding, Florida, where they are to offer their services for overseas duty.

"The guard is composed of the following Kings County personnel: 105 nurses, 17 surgeons, 14 men from the medical group, such as

Hospital News

Lessons Learned from the Boston Fire

IN their article entitled "The Cocoanut Grove Disaster in Boston," which appeared in the December 26 issue of the *J.A.M.A.*, Drs. N. W. Faxon and E. D. Churchill, Director and Chief, respectively, of the West Surgical Service of the Massachusetts General Hospital, have set forth several suggestions for the establishment of a catastrophe organization for all hospitals. Among other things, they advise:

1. "A well-planned and organized telephone service to notify hospital administration, staff, maintenance, and department heads"

2. "The immediate examination and separation of the living and dead at the very entrance of the hospital. . . . Two medical house officers were stationed at the door for this purpose."

3. "The organization and division of staff and nurses into teams for the undressing of patients, the care of clothes and valuables, the administration of morphine, the treatment of shock, dressing of burns and wounds, oxygen therapy, and surgical procedures."

4. The assignment of experts to the scene

of a disaster in order to determine the nature of the trauma, the presence of noxious fumes, etc., as an aid to the treatment of casualties. Immediate examination of the dead should also be started as a further means of assisting in the treatment of the living

5. The establishment of an emergency morgue. Consecutively numbered tags, bearing the date and hour of arrival, should be attached to the wrist of each body. In making identifications, only one group should be admitted at a time

Because they had been prepared for emergency work through the operation of Civilian Defense organizations, the directors of the Massachusetts General Hospital were ready to handle the catastrophe, but in ordinary times such organization might not have been so well established. As the authors point out, plans for the handling of emergency disasters must be made in every hospital, for "an emergency anticipated and prepared for ceases to become an emergency."

New York Nurses in Africa

AMONG the United States Army nurses who have arrived in North Africa are 52 women from New York, all members of the Roosevelt Hospital unit. The nurses are under the command of Second Lieutenant Edith Frew, who recently reported by letter to the Roosevelt Hospital on activities of the unit.

The unit includes representatives of nine New York hospitals—27 from Roosevelt Hospital; 6 from Doctors' Hospital; 5 from Lee's Sanitarium; 3 from City Hospital, Welfare Island; 1 each from Flower-Fifth Avenue Hos-

pital, Bellevue, St. Ann's Maternity Hospital, and Manhattan Ear, Nose, and Throat Hospital, and 2 from Queens General Hospital, Jamaica

The unit, also including 32 doctors, was organized in February by Lt. Col. Frank B. Berry, surgeon on the Roosevelt Hospital staff, and left for overseas duty in September, after participation in maneuvers in North Carolina. In October the unit arrived in England, where Lt. Col. William E. Stone, of the Missouri National Guard, assumed command

Improvements

According to the *Watertown Times* of December 26:

"Nothing stands in the way of early inauguration of construction operations for Massena's government-contributed barracks type hospital, hospital board officials felt today, with receipt of word from Congressman Clarence E. Kilburn that a War Production Board approval of needed priorities will be forthcoming by the first of next week.

"A government release of materials will clear the last obstacle holding up actual construction, it was pointed out, as the necessary agencies have given their approval, an architect's design has been accepted, the contract has been let, and the local board has secured the tentative services of personnel to staff the institution

"The barracks-type hospital, considered an emergency measure because of the lack of critical metals required for the postponed \$300,000 structure originally decided upon, will be constructed on the rear of the Maple Street plot donated to

the town last spring by Mayor and Mrs. R. A. Newton.

"As demands of the war procurement agencies cornered more and more of metal building materials, however, and the structure entered the "off-for-the-duration" class, the hospital board, headed by Assemblyman Allan P. Sill, accepted the government alternative of a temporary construction, which would ease the local burden until normalcy returned.

"Since the plan was accepted, lumber, too, has become a critical material, and the lack of needed priorities remained the last stumbling block to the inception of actual construction"

Construction of the 120 buildings of the 1,500-bed U.S. Army General Hospital on a 165-acre tract in Burrstone Road, Town of New Hartford, will be started at once, it has been announced by Maj. F. R. Deland, engineer in charge of the project for the government

* Asterisk indicates that item is from local newspaper

"At Kings County hospital they are proud as anything over the advance guard that has just left for Ft. Blanding, Florida, where they are to offer their services for overseas duty.

"The guard is composed of the following Kings County personnel: 105 nurses, 17 surgeons, 14 men from the medical group, such as

x-ray technicians, clerks, laboratory assistants and pharmacists, five dentists, three pathologists, and two roentgenologists.

"They'll form Base Hospital 37 and act in unison wherever sent. They are volunteers.

"The Army is appointing 12 men to form the administrative staff that travels with the unit.

"Heading the groups is Lieut. Col. Dr. George Dixon, of surgery. Topping the medical men is Lieut. Col. Arthur Frankhauser; heading the nurses' contingent is Miss Alice Gritsavage, former operating-room supervisor.

"They'll have their own ambulance, too."*

. . .

The Junior American Nurses have opened their new national headquarters at the Hotel Biltmore, in New York City.

According to Mrs. Dixie L. Dean, national director, the purpose of the organization is to prepare the girl of high school age for an im-

portant part in war work. She announced that plans soon will be initiated for opening nurseries throughout the country to care for the children of factory workers.

"We will train the young to care for the young," she said. "Young girls will take the children of workers to and from the nurseries and may care for them at night."

The first nursery will be opened in Jamaica, Long Island, in January.*

. . .

Dr. George S. Reiss has been chosen president of the Long Beach Hospital, the first physician ever to be elected to the post. Chief of the hospital's medical staff, Dr. Reiss was elected at the annual meeting in the hospital auditorium on December 7. He succeeds Leo Gerstenzang, who was named honorary president of the institution.*

USEFULNESS OF LAUGHTER

Laughter is dependent upon a reasoning power and sense of deduction. It is physiologic, and it is natural.

Laughter may thus be said to be an integral part of the physiologic processes of the body and mind, and, as such, should be practiced more and more. Laughter and pleasant thinking should then be considered a valuable adjunct to all-round healthy living as well as a natural, easy means of total physiologic exercise easily within the reach of all.

Finally, laughter begets optimism and self-confidence, and relegates fear and pessimism to the background. It is a well-known fact that the self-confident, happy, optimistic contestant, whether it is in athletics, mental con-

flict, or any other phase of life, has a distinct advantage both physical and mental over an opponent who is not so fortunate as to possess these qualities.

It may be that in the future we will realize more and more the importance of a hearty laugh and its attendant chain of supporting by-products. We may eventually evaluate the true balance of spare time, call it what you will—vacation, deviation from the humdrum path of daily work, or just plain loafing—and then recognize the fact that accomplishment will be measured by such standards rather than by long hours of drudgery amid tobacco ashes, empty coffee pots, and, in some cases, empty flasks.—E. Forrest Boyd, M.D., in *Southwestern Med.*

Steps to Check Emotional Ills Being Planned*

A vastly increased application of the comparatively new science of industrial psychiatry, bringing major social and economic benefits, will be another development of the new industrial pattern emerging from the war effort, in the view of Dr. Lydia G. Giberson, industrial psychiatrist of the Metropolitan Life Insurance Company and a pioneer in the field.

Dr. Giberson, a Canadian-born scientist who took her present post eleven years ago and since has campaigned nationally for the sociomedical program in industry, is seeing the groundwork laid by herself and other trail blazers now being widely studied for inclusion in the war production system in her additional capacity as a consultant to the Office of Emergency Management at Washington. She is averaging two days a week in conferences at the capital and also maintaining her contacts with other organizations taking part in the program.

"Virtually all the government agencies and an increasing number of industrial groups have now recognized the importance of proper safeguards and controls for maladjusted emotions of war workers," Dr. Giberson said, "and it is inevitable that something effective will be done despite the current lack of a complete program and rounded organization. . . .

Cites Pressing Dangers

"The dangers of our war-time industrial upheaval are only too evident and immediate. Hysteria, excessive fatigue, emotional maladjustment, use of marginal labor groups, crudities of green authority, racial antagonisms, propaganda, subnormal housing, uprooted social patterns, and fear of bombings are problems fully admitted. Psychiatric conservation of manpower is urgently needed."

Details of any large-scale and coordinated measures for application to American industry of a science that has been largely restricted to the comparatively wealthy remain to be evolved, but it is anticipated that a considerable contribution will be made by presently active industrial physicians.

Their scope and responsibility would be broadened under tentative plans to provide the psychiatric services of listening to workers' woes (in itself a valuable therapeutic aid), tracing the emotional complications of routine medical patients, diagnosing industrial trouble spots, recognizing the obvious maladjusted types, spotting accident repeaters, helping to prevent maladjustment by advice—partly by bringing the extra-industrial factors to bear on any interpretation of employee difficulties—and conserving manpower and upholding morale through fighting to secure medical immunity for the emotionally ill.

Dr. Giberson in her government work has noted the emergence already in this country of "war types" of sick personalities earlier familiar to England. She describes some of these as "(1) the upset ritualist, who, having lost his balance wheel, wears a ruffed temper until he can surround himself with a settled routine; (2)

the excited enthusiast, who burns himself out quickly and does his best to persuade others to do likewise; (3) the emotional expansionist, usually a quiet and even prim fellow, who becomes obscurely excited by war dangers and plunges into all sorts of uncharacteristic excesses including drunkenness and wasteful spending; (4) the *nouveau* bellicose, who suddenly finds a voice and proceeds to exaggerate every topic with a blood-thirsty animosity, his government and the war effort included; and (5) the deaf-static, who is deeply alarmed by the turbulency and danger and yet closes his mind to them by hugging the familiar things of a safe existence so feverishly that there is no juice left in them for him."

Curative Setup Lacking

These obviously are behavior patterns and not mental or emotional types, she added, but are no less important, and their detection and care are extraordinarily difficult through the present dispersed procedures.

Furthermore, under the stress of war industry's pace, following the common economic and engineering conception of the worker as a mere handle to a machine in pre-war industry's mushroom growth, mere "drives," appeals to "morale," and "recreation" projects hardly will fill the need, Dr. Giberson says. There must be, she declares, tested procedures of synthesized medical and psychiatric practice to combat what she calls the "emotional blackout" of the man who, although in his off-the-job life a fully rounded individual, becomes within the factory gates a "selfless unit employing only a fraction of himself, working with another man's tools on a product which will not bear his name and whose function he barely comprehends."

Actually, she said, some 25 per cent of pre-war workers would have benefited, as well as their employers and the community, by psychiatric attention, even though they did not come within the classification of the psychotic. The pressures of the war, she believes, will move this figure up to 40 per cent.

Dr. Giberson, who is a frequent speaker on women in war industry, does not share altogether the gloomy views of some sociologists respecting the predicted employment soon of an additional 5,000,000 women in war industries. Despite the by products of increased family dislocation, lessened mother care of children, and similar phases, wholesale war employment will bring to American women, she says, a basic progress of unprecedented proportion.

Creator of Stability

"Women," she said, "have been demanding equality, and the war emergency provides an opportunity for them to take equal responsibility too. It is doing more for women's stability than anything else in providing an outlet for the pent-up strains of the defense period and those that have followed through restoring the pioneer virtues of work and sacrifice and in providing self-expression through independence. This is a people's war and the front is everywhere. There

REVIEWED

Principles of Extraperitoneal Caesarean Section. By James V. Ricci, M.D., and James P. Marr, M.D. Octavo of 224 pages, illustrated. Philadelphia, The Blakiston Company, 1942. Cloth, \$4.50.

In this book the authors discuss in detail the anatomy and technic of extraperitoneal caesarean section. Its indications are not discussed. The history of the development of this operation is completely presented; in fact, it is so well done, so clearly, and in such excellent sequence that it is very easy reading.

The authors state that E. W. Cartwright of Pasadena deserves the credit for the Water's operation, which has lately become so popular. Ricci's own operation, which does not differ greatly from the Water's technic, is described, but his illustrations are not so good as those of Water's. Ricci prefers the Pfannenstiel incision, dislodges the fetal head from below, and packs the vagina stiffly with iodoform gauze before making his incision.

Piquant sentences like "DeLee piped a eulogy to craniotomy" and "Data was rebashed in a somewhat sketchy form by L. C. Phaneuf" add nothing. Errors like "W. C. Danford," "entrotitus," "laparotomized," "cesareanized," and "operated" are unfortunate. However, the book is good reading for the serious obstetrician.

CHARLES A. GORDON

Dermatologic Therapy in General Practice. By Marion B. Sulzberger, M.D., and Jack Wolf, M.D. Second edition. Octavo of 632 pages, illustrated. Chicago, Year Book Publishers, 1942. Cloth, \$5.00.

The average medical practitioner of today has been taught less and usually knows less of dermatology than of any subject in the category of medical knowledge. And yet, in active practice diseases of the skin are met with too frequently and too often to warrant this meager preparation. Those who have had some train-

ing as students may gain some valuable knowledge in the diagnosis of the commoner diseases of the skin, but of what benefit to the patient is the identification of the disease if the physician's skill stops there? Once the diagnosis is made, recourse to one of the textbooks or some formula may indicate a dozen remedies, but how few of them are explicit in describing how the remedies should be applied! The first edition of this work took its place very quickly as a handbook on the subject, and the new edition still further enhances its value as such.

The first three parts of the book are given over to the principles of diagnosis, topical medication, the uses of the physical agents, and general medical management. These chapters alone constitute a training course in clinical management of the greatest assistance to those who have not enjoyed the benefit of attendance in one of the larger dermatologic clinics.

Space will not permit of the exposition of the many and indispensable suggestions, proved prescriptions, short cuts, and clever methods for preparing and applying dressings which this volume holds. The illustrations are many and excellent. It is impossible to conceive of a textbook better fitted to supply the proper dermatologic information to those of our number who are now being drawn into war work, and it is pleasing to note that Admiral Ross T. McIntire, Surgeon General of the Navy, has seen fit to recommend this book.

Among the special subjects that Dr. Sulzberger's extraordinary training has best fitted him to write on are allergy and the treatment of syphilis.

NATHAN THOMAS BEERS

Personality and Mental Illness. An Essay in Psychiatric Diagnosis. By John Bowlby, M.D. Octavo of 280 pages. New York, Emerson Books, Inc., 1942. Cloth, \$2.75.

New approaches to the study and understanding of personality deviations are always welcome and oftentimes illuminating. This is true of Dr. Bowlby's discriminating analysis and formulations for better realistic and practical evaluations of varying degrees of mental illness. The author has ingeniously and critically brought to the front telling personality traits of mentally sick persons, rather than their symptoms, as a basis for bringing order into psychiatric diagnosis and classification. His method is clearly illustrated by several charts which give details of specific personalities. He groups them: "schizoid traits," "nonspecific traits (depressive)," and "nonspecific traits (hyperthymic)." It is significantly revealing how these charts with their plus or minus sign, and occasionally an asterisk, not only aid in crystallizing a diagnostic concept but also give prognostic implications.

We are indebted to Dr. Bowlby for courageously cutting through traditional clichés and conceptions of all-too-circumscribed diagnostic entities. On the basis of thorough case studies and follow-up notes of patients who came under his care, beginning at the Maudsley Hospital in 1933, the author clarifies the differentiating and blending relationships of psychoses to each other and also to neuroses. Clinical study in personality trait

charts, form the basis of a proposed new classification of the neuroses.

Specialists in psychiatry will be pleased to have this succinct, highly readable summary of the advances in psychiatric knowledge, and particularly the author's personal, unbiased criticism of outstanding contributions to psychiatric literature since the turn of the century. It is a book that especially appeals to the research worker in psychiatry, as well as to the clinical psychiatrist and to all those working in the field of personality deviations of the more or less pronounced type.

FREDERICK L. PATRY

Biological Symposia. A Series of Volumes Devoted to Current Symposia in the Field of Biology. Edited by Jaques Cattell. Volume VII, "Visual Mechanisms." Octavo of 322 pages, illustrated. Lancaster, The Jaques Cattell Press, 1942. Cloth, \$3.25.

This work is a high caliber report on recent advances in the physiology of vision. It begins with a discussion of the energy relation in vision, discusses the photochemical background of visual purple, reviews our present concepts of Vitamin A in relation to vision, and discusses the influence of oxygen deficiency in relation to the visual system. These chapters alone make evident the clinical possibilities of this technical subject, and the relation is further carried on in the following chapters having to do with the anatomy and physiology of the optic pathways and of functional organization of the occipital lobe.

Although this entire volume is definitely technical, and little of the work is done by ophthalmologists, it is, nevertheless, very understandable and certainly presents much useful material for the ophthalmologists.

The reviewer believes that work of this type forms a basis for progress in pure ophthalmology. The work should be in every ophthalmologist's library.

JOHN N. EVANS

Acute Injuries of the Head: Their Diagnosis, Treatment, Complications and Sequels. By G. F. Rowbotham, B.Sc. Quarto of 288 pages, illustrated. Baltimore, Williams & Wilkins Company, 1942. Cloth, \$7.50.

This is a timely volume for the general surgeon who is frequently confronted with head injuries in these days of motor cars and war. Professor Rowbotham, having had extensive experience as a neurologic surgeon in peacetime, has, ever since the German attack, gathered much information on the open brain injuries characteristic of war.

The importance of teamwork between the neurologist, the psychiatrist, and the surgeon is emphasized and explicit details of diagnosis and treatment are given. His work has crystallized the thought of the English profession and led to the establishment of "head injury centers." We in America can learn much from this excellent example, but there is one important factor of difference here and abroad. Professor Rowbotham urges that all patients with serious head injuries be moved immediately to these centers,

holding that the transportation will do them no harm. Here where distances are so much greater, the reviewer feels, from his limited experience, that the patients will, on the average, do better if they are moved as little as possible even though this may mean less expert and less active surgical intervention.

A plan may be worked out in this country whereby the expert neurosurgical team could be taken to the patient, by air if necessary. If this should prove feasible, it would eliminate the added insult of moving patients with serious head injury and yet a large territory could be covered with a limited personnel.

WILLIAM H. FIELD

Medical Progress Annual. Volume III, 1942. A Series of Fifty-two Reports on the Recent Accepted Advances in Diagnosis and Treatment. Published during 1941 in *The New England Journal of Medicine*. Managing Editor—Robert N. Nye, M.D. Octavo of 678 pages, Springfield, Charles C. Thomas, 1942. Cloth, \$5.00.

The articles on medical advances, in the year 1941, which appeared in the *New England Journal of Medicine* each week, are here collected for the third time in a well-bound, moderately priced volume.

The papers cover a variety of subjects, from bacteriology to radiotherapy, and represent the opinion of outstanding men in Boston.

The volume is distinctly worth while and profitable reading.

ANDREW M. BABEY

Facts for Childless Couples. By E. C. Hamblen, M.D. Duodecimo of 103 pages, illustrated. Springfield, Charles C. Thomas, 1942. Cloth, \$2.00.

This little book with a very attractive cover is intended to educate the sterile couple. It bespeaks their cooperation with the physician they may consult, and tells them what to expect from him. In clear, simple style, anatomy and function are explained, and technical procedures are outlined.

This ABC of sterility is an excellent book for the physician to recommend to his patients. The general practitioner and the medical student will find it profitable reading, too. The standing and reputation of the author guarantee its accuracy.

CHARLES A. GORDON

First Aid, Surgical and Medical. By Warren H. Cole, M.D., and Charles B. Puestow, M.D. Octavo of 351 pages, illustrated. New York, D. Appleton-Century Co., 1942. Cloth, \$3.00.

This advanced guide to first aid put out by the University of Illinois is an excellent volume. It gives considerably more detailed facts on the usual topics covered by elementary manuals and is well illustrated.

ANDREW M. BABEY

[Continued from page 177]

isn't any place to run. A job for every man, woman, and child is the best safety valve for wartime emotional strain. Women show their best colors under stress, and this is no exception."

Dr. Giberson applauded the girls and women in service and volunteer uniforms, but added: "My respect goes, too, to the girl in overalls and goggles on the assembly lines. It is much harder

to check glamour in the factory locker and stay in a hard job."

For women troubled by war problems in industry or home, she says: "Try to keep your sense of humor. If you are doing all you can in the war effort, don't deny yourself normal relaxations and a new hat. Find comfort in sacrifice and working for victory. Return to the simple things. All must work, and none must weep."

AN OLD TIMER CARRIES ON!

The esteemed, venerable practitioner is still carrying on! In many instances, our old friends are coming out of retirement to fill the gaps resulting from enlistment of their younger colleagues in the armed forces.

Another old friend and veteran in the armamentarium of the practitioner, Arsenoferratoze, is also carrying on! Modern therapeutics recognizes the value of Arsenoferratoze in the treatment of the anemias found in pregnancy, parturition, lactation, x-irradiation, and chronic hemorrhagic and iron deficiency diseases.

In addition, today's needs have logically extended the indications for Arsenoferratoze... To counterbalance

the blood changes in sulfa-drug therapy . . . To act as a replacement factor for blood donors . . . To safeguard against iron deficiency in the restricted diets of defense workers.

The old practitioner specifies Arsenoferratoze because it has "proved its metal" in many years of service. He knows that it is pleasant to take, easily and readily assimilated, and decidedly non-irritating. Arsenoferratoze serves a dual purpose—acting as an efficient hematinic and as a suitable alternative. Its palatability makes it especially suitable for children.

ARSENOFERRATOZE
HEMATINIC AND ALTERNATIVE OF CHOICE

Dosage: One to three teaspoonfuls, 2 or 3 times daily, with meals. *Supplied:* plain, or with copper, in bottles of 8 fluid ounces; in tablets, bottles of 75.

Rare Chemicals, Inc. FLEMINGTON, N. J.

SAMPLE AND LITERATURE WILL BE SENT TO PHYSICIANS ON REQUEST

Tuberculosis and the War—Here and Abroad*

The United States

The world conflict of 1914–1918 for the first time revealed tuberculosis as a major problem. From the early discovery of large numbers of tuberculous troops in the French army to the final assemblage of mortality records of the war years in the civilian population of all countries engaged, it was evident that tuberculosis was exacting a great toll, unrecognized in the wars of previous years. There is every reason to believe, however, that long wars accompanied by privation have always led to increase in tuberculosis. Crowding, malnutrition, exposure to infection and hardship of every sort have been considered responsible in different degree.

Fortunately, a quarter of a century of research since the last World War has led to a better understanding of methods for control of tuberculosis. Countries fearing the ultimate outbreak of hostilities, through the tense years preceding their final advent, anticipated tuberculosis as a grave menace and prepared accordingly. But in spite of forewarning and preparation, a rise in tuberculosis mortality rates appears already evident. Modern war is total war. Whole populations are engaged, through accelerated industry as well as actual combat.

In the present World War increasing effort is being made in the United States to avoid induction of soldiers with tuberculosis. Measures ensuring x-ray examination of practically all recruits admitted to the armed forces are in effect.

In the civilian population precautions are being taken against nutritional deficiency, since it is almost universally believed to have important bearing on the problem of resistance to tuberculosis. However, malnutrition may not be the gravest predisposing factor in a rise of tuberculosis. The acceleration of industry, leading to crowded quarters in industrial districts, brought about by the mass migration to industrial centers, has created another opportunity for widespread infection. It is evident that a grave menace exists of another world-wide recrudescence of tuberculosis. Its prevention will require vigorous effort against the spread of infection and all measures possible to maintain a high level of resistance to disease.

War and Tuberculosis, Esmond R. Long, Amer. Rev. of Tub., June, 1942.

Britain

To what extent the tubercle bacillus will repeat its former triumph of a generation ago in Britain cannot yet be properly gauged, but it has taken the initiative and the future course of events will be greatly determined by the effort put forward now by tuberculosis workers.

Deaths from respiratory tuberculosis increased about 6 per cent the first year of the war and 10 per cent the second, while the increase in deaths from other forms of tuberculosis was 2.4 per cent the first year and 17.6 per cent the second.

A considerable amount of infection is evidenced among the general population, particularly children, which means that either the

infecting dose is large, or the resistance low. Both causes may have operated in the first half of 1941 when the nightly bombing of towns and cities made contact infection probable and frequent. However, if the increase is found to have continued since more normal conditions have prevailed, it will strengthen the idea that there has been a general lowered resistance to infection in children under five. Many factors can have contributed to the lowering of resistance in children, among which are change in diet, non-pasteurized milk, blackout and shelter conditions and lack of sleep and rest.

Comparing the trend of events during the first three years of the last war and available figures for World War II, a definite similarity can be traced, although living conditions now are probably more conducive to the spread of tuberculosis. However, there are some marked differences. Tuberculous meningitis has increased sharply, whereas in the corresponding period of the last war it fell almost to the pre-war level. A further point of difference is the small variation between the male and female curves.

These are ominous signs which mean that infection is lurking in hidden places taking its toll, especially in infant lives, and which emphasize the urgency of means for discovering these nests of infection and the need for their adequate control.

A Further Review of Tuberculosis in Wartime, F. Heaf and L. Rusby, Tubercle, May, 1942.

France

Food rationing started throughout France on October 1, 1940, when the following foods were restricted: bread, meat, cheese, fats, sugar, milk, chocolate and milled products. Technically other foods could be obtained, but in reality it was difficult to get them. The results of a survey carried on by the Institut des Recherches d'Hygiène on how different families of Paris were feeding themselves showed a total caloric insufficiency of about a thousand calories daily, a calcium deficiency and a calcium-phosphorus imbalance and an insufficient intake of Vitamin A.

Undoubtedly morbidity and mortality from tuberculosis have noticeably increased in Paris. The percentage of rapidly developed tuberculosis has gone up in an alarming manner. Comparing the figures of the first six months of 1941 with the corresponding ones in 1939, the mortality from tuberculosis increased 10 per cent.

Four basic diets were prescribed for sick persons in four specific categories. To lessen the ill effects upon persons with active tuberculosis and known lesions, a diet was given which corresponded to their general category, plus a supplementary amount of 45 Gm. of meat and 15 Gm. of fat daily per patient. Despite the precaution indicated, the march of tuberculosis up to October, 1941, had been ominously progressive; thus if the present dietary regime continues and the consequences increase, the problem of tuberculosis in France will be exceedingly grave.

Food Rationing and Mortality in Paris, 1940–1941, Ramon F. Minoli, Milbank Memorial Fund Quarterly, July, 1942.....

* Tuberculosis Abstracts—A Review for Physicians, Issued Monthly by the National Tuberculosis Association, 16: No. 1 (January) 1943.

THE PHYSICIANS' HOME

WHO STARTED IT? A group of physicians in 1918. They recognized the tragedy of their colleagues who were destined to go to local or state charitable agencies. The purpose was to establish and create means, to offer help, and maintain self-esteem for those deserving professional men and women. *THE PHYSICIANS' HOME represents the efforts of this group.*

WHOM DOES IT SERVE? Members of the medical profession of New York State, on recommendation from their local county medical society.

WHERE DOES IT SERVE? In their own community or as our guests.

WHO ARE OUR GUESTS? Aged, indigent physicians in good standing or widows of physicians.

WHO SUPPORTS IT? Members of the medical profession in the State of New York by voluntary contributions and legacies.

We appeal to the profession for continued support for this worthy charity

Make checks payable to: THE PHYSICIANS' HOME, 52 E. 66th St., New York

ONE "STAPLE" WE CAN GIVE UP

Even if you are not in the publishing or printing business, you may have heard or noticed that magazines and booklets have been taxed one binding staple for the duration. This, of course, to conserve metal for war use.

One measly little staple help the war effort? Let's figure it out.

The *Saturday Evening Post*, receiving seven complaints about pages of the magazine falling out, decided to give readers a little light on the subject. So complainants might be advised how important this sacrifice of one staple in each copy is, they started computing the amount of metal saved. One staple saved in each copy, multiplied by the number of weeks in a year, multiplied by the circulation figure of three mil—but here the astronomical numbers started to "stump the experts," so they consulted the manufacturing department.

The editors learned that a three-stitched *Post* had required some forty-five tons of wire a year, so the annual one-stitch saving amounts to one-third of that, or fifteen tons—enough steel for one thousand 105-mm. shells. Multiply the saving by the thousands of periodicals and booklets published in the United States and you will find enough material salvaged before it becomes scrap to help put teeth in a great number of vital weapons.

Remember this when "the leaves begin to fall" from your favorite publications and don't think harshly of the publisher. And don't scoff at any effort to save material for more serious purposes—no matter how insignificant it may appear on the surface.

IN THE ADS

"first basic discovery in 55 years—Sand has always been a basic ingredient of optical glass. Now, for the first time, Kodak is making optical glass of 'rare elements'—tantalum, tungsten, and lanthanum. No sand—to the optical scientist, it's 'almost as revolutionary as discovering how to make steel without iron.'"—*Eastman Kodak Company*

* * *

"They'll give you a fresh start in life—"This is a Na court. Maybe none of us will ever have to face one . . we hope.

"They specialize in giving people fresh starts in life. All that you've ever had . . your home, your bank account, the very clothes off your back, your family, even your self-respect . . they take from you.

"They start you off fresh, with nothing. They don't even leave you the opportunity you have now.

"Millions of people have gotten fresh starts at the hands . . millions of human beings who have worked and scrimped and saved all their lives for a little comfort a mere modicum of happiness and security. Millions of men and women in Poland and Russia and France. Millions like us. . .

" . . there is no time to wait to be told what to do. Each of us must find out what to do and do it. For with every minute, every precious minute, the decision grows closer. Win or lose. Have or have not. Live or die.

"Not just for the other fellow. For you. . . ."—*American Locomotive*

CROSS REFERENCE . . . It may be necessary at times to check the information provided in an advertisement on some particular product to be prescribed. To facilitate this a cross index of advertisers and advertised products is published in every issue of the JOURNAL. We hope you will find it a convenient and useful instrument. In this issue see pages 103 and 112.

AN "ESSENTIAL NONESSENTIAL"

Mary Elizabeth Parker (*New York Times*, Dec. 20) remarked that economists may frown on the huge outlay for cosmetics in wartime, but the specialists in matters of morale take a different view.

Mentioning the \$517,500,000 spent in this country during 1941 by our women for paints, powders, and perfumes, Miss Parker intimated that the 1942 expenditure for beauty products will surpass even that tremendous figure. Statistics on such frivolous matters compiled by the Federal Reserve Bank estimated that women bought 10 per cent more powders and lotions in October, 1942, than during the same month of the preceding year. In defense areas the increase was even greater.

"The question is," said Miss Parker, "is beauty worth it?" To find some justification for such seeming waste, the results of a poll of male opinion were reported.

C. A. Willard, deputy chief of the Cosmetics Branch of the W.P.B., voiced the opinion—"Good heavens, most of it doesn't do any good, anyway! We'd hardly want to sacrifice the war effort to a tooth whitener."

Mayor LaGuardia's opinion was "don't like the red stuff on fingernails, anyway."

But men engaged in the nation's war industries did not agree with such thoughts. John Happel, Jr., a chemical

engineer, working on the development of synthetic rubber, said—"Yes, of course it is justified. We probably spend a heck of a lot more on cigars and cigarettes—and the results aren't nearly as attractive."

A flight instrument engineer declared a half a billion is well worth it. "Every girl in our plant wears make-up and it looks darned nice. It really gives you a lift every time you go into the shop."

Service men in the Navy and Coast Guard also said they thought the expenditure was worth while, but "they ought to taper off on lipstick—wear the kind that doesn't come off." And a half a billion was a little too much.

Professionals in the matter of morale were more lenient. Dr. Iago Galdston of the Academy of Medicine termed the woman's make-up as an "essential non essential." One of the greatest threats to civilian morale, he felt, is the interruption of familiar personal routines. "After all," observed Dr. Galdston, "neckties aren't exactly essential either. And yet no one has put a taboo on them—even in England. And you know they kept right on showing motion pictures over there, even during the very worst periods of bombing."

Physician in Charge

[Continued from page 185]

A physician and consultant to the Medical Information Bureau believed that vanity is an indestructible feminine instinct which might just as well be reckoned with. "If you want an idea how essential this instinct is, just look how the average woman will juggle her budget to include cosmetics," he said. "That's a fair index. She would rather have a lipstick than eat, if it comes to a choice—and often the lipstick will be an expensive one."

A psychiatrist, Dr. Richard Hoffman, contended that applying lipstick and powder is like laughter—it belongs on the "plus side" of emotional experience, meaning that it produces a stimulation of the thyroid and adrenal glands, a restoration of sugar to the blood and actually serves to counteract fatigue. "Efficiency engineers," Dr. Hoffman pointed out, "have discovered that because of these strange chemical occurrences, a dressing room established for primping purposes in a busy factory may improve efficiency to the extent of 10 or 15 per cent."

This contention has been substantiated by the experience of the British. At the beginning of the war, in order to effect economies in war materials, the British Government restricted the manufacture of cosmetics to one-fourth of peacetime production. The result was a decline in war factory records and an increase in ill

health largely due to "bootleg" cosmetics that were oftentimes injurious. When cosmetic stations were established throughout the industries, the production curve soared immediately and increased numbers of women flocked to the war factories to work. A recent regulation order that girl workers in British munition plants shall wear and apply cosmetics three times a day as protection against infection and discoloration. Cosmetics for this purpose are supplied by the Government.

Here we expect to benefit from the experience of the British in this matter as we have in so many other war problems. If there is to be any restriction at all, it is to be on the use of ingredients vital to fighting the war. To overcome this obstacle, our cosmetic chemists are unearthing a substitute for the missing ingredient—and sometimes even a substitute for the substitute.

"As long as the women of this country continue to want cosmetics—and they always will—the chemists will continue to supply them," declared the research director of one of America's largest drug houses. "Gradual evolution in buying habits may come about. There will probably be more preparations of the sensible, protective sort. That means fewer throat bleaches and eyebrow creams, and fewer fabulous prices paid for labels marked 'made-in-France.' But there will always be cosmetics."

FALKIRK IN THE RAMAPOSS

A sanitarium devoted exclusively to the individual treatment of MENTAL CASES. Falkirk has been recommended by the members of the medical profession for half a century.

Literature on Request

ESTABLISHED 1889

THEODORE W. NEUMANN, M.D., Phys-in-Chg.

CENTRAL VALLEY, Orange County, N. Y.

WEST HILL

West 252nd St. and Fieldston Road
 Riverdale-on-Hudson, New York City

For nervous, mental, drug and alcoholic patients. The sanitarium is beautifully located in a private park of ten acres. Attractive cottages, scientifically air-conditioned. Modern facilities for shock treatment. Occupational therapy and recreational activities. Doctors may direct the treatment. Rates and illustrated booklet gladly sent on request.

45 Totowa Ave. PATERSON, N. J. Armory 4-234

THE CARGO CARRIER OF TOMORROW?

Movement of freight by air was given little serious consideration until the new conditions of the war developed. This is partly because transportation problems have become acute so that despite high costs serious consideration is now given to air freight transport for emergency situations.

W. A. Patterson, president of the United Air Lines, refutes any idea that air cargo ships will supplant surface carriers, and he points out facts that prove the airplane freight line will not soon be a serious competitor. As a comparison between the surface and the air carrier, Mr. Patterson used actual peacetime conditions.

Says Mr. Patterson, "The average freight train would consist of 50 cars, thirty of them loaded with 26 tons of freight each, and 20 of them empty. Such a freight train, based on actual railroad statistics for the year 1940, would carry a total of 780 tons of revenue cargo. Operated between Chicago and San Francisco, it would give sixth morning delivery and could make two round trips in a month's time.

"Therefore, every month it would deliver a total of 1,560 tons each way between those two points. An oil-burning locomotive pulling this train would consume 170,000 gallons of fuel oil during the month, which at 2 cents a gallon would cost \$3,400. The operating crew on such a freight train would number five men and the equivalent of four crews or twenty men would be required to keep the train running. Their total pay would be approximately \$5,000 for the month. The total operating cost of the train based on 1940 railroad experience would amount to \$50,000 for the month, which represents the cost of moving 1,560 tons by rail from Chicago to San Francisco, and another 1,560 tons from San Francisco to Chicago during the interval of a month, or two round trips.

"Now let us do the same job by airplane, using familiar Mainliner type of equipment which is now in on our line, but converting it to a cargo-type airplane. The average lifting power of such an airplane would permit it to nibble in small bits of only 2 1/4 tons each at 1,560-ton pile of cargo moved by the freight train in month's time. It would take 626 bits of 626 round-trip flights by this airplane between Chicago and San Francisco—to do the same job that the freight train did two round trips. This represents 2,500,000 miles flying compared to 8,880 freight train miles.

"Obviously, a single airplane could not make many round trips between Chicago and San Francisco a month's time. Normal operating experience would indicate 11 round trips per month per airplane as average. On this basis, 57 airplanes would be required to do the job of the freight train. During the month these airplanes would consume 1,500,000 gallons of gasoline, compared to the 170,000 gallons of fuel used by the train. The gasoline would cost a total of \$200,000 compared to the \$3,400 for fuel used by the train. For hundred pilots would be needed to fly the airplanes against 20 crew members used to keep the train running. The pilots would receive a total of \$200,000 in pay for the month, while the payroll of the train crew would amount to \$5,000.

"Based on recorded experience, the total operating costs of the 57 airplanes would amount to \$1,750,000 during the month while the freight trains costs would be \$50,000. The airplane operation would therefore cost 35 times as much as the freight train operation."

So for some time yet, the old "iron horse" has little to fear from the wings that make him a snail in comparison—at least not in carrying cargo.

FROZEN FOR THE DURATION

"A man is never so happy as when the women in his life are at peace with each other. His mother, his sister his daughter, his wife, a favorite aunt, even his grand mother—the women in his life have a lot to do for every soldier they have seen on his way to the front. Those letters that follow him there, must contain no hints of feminine bickerings or disagreements going on in the household he has left behind. Worth countless tins of cookies, is the happy reassurance that all is well at home and so, in the best military interests, all mother-in-law jokes and in-law problems should be frozen for the duration."—From the notebook of Elsa Conners.

Celiac Disease Yields to New Treatment—

VITAMIN B COMPLEX (PARENTERAL)

Lederle

Before Treatment

After Treatment

STUDIES RECENTLY CARRIED OUT* reveal that celiac disease is probably a deficiency disease. Impairment of absorption of necessary factors, rather than low intake seems to characterize this syndrome. When "Vitamin B Complex (Parenteral) Lederle" and Liver Extract were administered intramuscularly, absorption of fat and glucose, as well as intestinal motility and the clinical course, were favorably influenced; and these results were achieved *within three to six weeks*.

"Solution Liver Extract (Parenteral) Lederle" may be used together with "Vitamin B Complex (Parenteral) Lederle" according to the plan of therapy outlined*. After the capacity to absorb has been restored, usually in three weeks, oral vitamin B complex therapy may be sufficient.

The significance of this plan is emphasized by the fact that the Department of Pensions and National Health of the Canadian Government sent on Sept. 28, 1942 a circular letter to all medical doctors in Canada, outlining this method of treating celiac disease.

*MAY, C. D., McCREARY, J. F., and BLACKFAN, R. D. J. *Pediat* 21: 289—Sept., 1942.

PACKAGES:

"Vitamin B Complex (Parenteral) Lederle" (each cc contains
Thiamine Hydrochloride (B₁), 5 mgm., Riboflavin (B₂), 0.3 mgm., Nicotinamide, 10 mgm., vitamin extracts derived from 55 Gm. fresh liver, supplying not less than 0.45 mgm. Pyridoxine (B₆) and 1.7 mgm. Pantothenic Acid).

1—10 cc vial

"Vitamin B Complex Tablets Lederle" (each tablet contains
Thiamine Hydrochloride (B₁) 2.0 mgm., Riboflavin (B₂) 2.0 mgm., Pyridoxine (B₆) 0.5 mgm., Pantothenic Acid 5.0 mgm., Nicotinamide, 10.0 mgm., vitamin extracts derived from 8 Gm. fresh liver).

Bottles of 25, 50, 100 and 1,000 tablets

"Solution Liver Extract (Parenteral) Lederle"
3-3 cc. vials (10 U.S.P. Injectible units each)

YOUR FRIENDS WITH THE FIGHTING FORCES

*Send them the cigarette that Rates First! **

IN camps at home...at the fighting fronts...the cigarette is a military institution...a comfort to all...a special solace to the wounded...and attending doctors, too.

Small wonder that service men appreciate cigarettes above all other gifts...and, by actual survey*, Camel is the favorite brand of men in our

armed forces...for mellow mildness, for clear, full flavor.

Your dealer features Camels—see or telephone him today.

* With men in the Army, Navy, Marines, and Coast Guard, the favorite cigarette is Camel. (Based on actual sales records in Post Exchanges and Canteens.)

REMEMBER, you can still send Camels to Army personnel in the United States, and to men in the Navy, Marines, or Coast Guard wherever they are. The Post Office rule against mailing packages applies only to those sent to the overseas Army.

Winter time is the season of throat affections. Many physicians have found Thantis Lozenges to be effective in relieving throat soreness and irritation, because they are antiseptic and anesthetic for the mucous membranes of the throat and mouth.

Thantis Lozenges

contain Merodicein (H. W. & D. Brand of Diiodooxymercuriresorcinsulfonphthaleinsodium), 1/8 grain, and Saligenin (Orthohydroxybenzylalcohol, H. W. & D.), 1 grain. They dissolve slowly, permitting prolonged medication with the two active ingredients.

Thantis Lozenges are effective, convenient and economical.

Thantis Lozenges are supplied in vials of twelve lozenges each.

LIPIODOL in X-Ray Diagnosis

The introduction of Lipiodol considerably broadened the diagnostic value of roentgenography. During the past two decades, a vast bibliography has been accumulated. A large number of investigators have evolved many technics for its application. Through its use, many deviations from normal are diagnosed which otherwise would remain undetected.

Lipiodol in bronchography

Lipiodol in hysterosalpingography

Lipiodol in paranasal sinus visualization

Lipiodol has been instilled into virtually every cavity or viscus of the human organism. Containing 40 per cent iodine in firm chemical combination with poppyseed oil, it is highly radiopaque, casting a dense shadow on the roentgen film.

Lipiodol is widely used in the roentgenographic exploration of the paranasal sinuses, the bronchi, the uterine cavity and the fallopian tubes, the spinal subarachnoid space, joint spaces, and fistula and sinus tracts. It is virtually nonirritating, and if retained in situ, is slowly broken down and its iodine is excreted via the kidneys.

Physicians are invited to send for a complimentary copy of the brochure "The Applicability of Lipiodol in Roentgenography and the Technic of its Use," which describes in detail the many uses of Lipiodol.

Lipiodol in soft tissue sinuses

Lipiodol in fistula tracts

Lipiodol in roentgen exploration of empyema cavities

Lipiodol in sialography

Lipiodol in myelography

LIPIODOL (LAFAY)

Lipiodol is supplied in a variety of ampule sizes and in a 20cc. vacuine type vial for economy of use.

THE CARE OF THE

Past experience in the management of arthritis demonstrates the importance of persistence in a well-planned course of treatment.

Since chronic arthritis is a systemic metabolic dysfunction with local manifestations in the articular structures, it requires intensive and prolonged systemic therapy.

With ERTRON, a safe and effective course of therapy is practicable. ERTRON is relatively non-toxic and may be given, therefore, in high dosage for as long a period as is necessary to produce optimum alleviation of the arthritic syndrome.

Palliative methods may be used in conjunction with ERTRON therapy without incompatibility.

Publications on "Classification of Arthritis" and "Differential Diagnosis of Chronic Arthritis," together with reprints of clinical reports, are available to interested physicians on request.

ERTRON*

ERTRON, the only high potency, activated, vaporized ergosterol (Whittier Process), is made only in the distinctive two-color gelatin capsule.

ERTRON is promoted only through the medical profession.

The Popularity of

THESODATE (*Brewer*)

(the original enteric-coated tablet of Theobromine
Sodium Acetate)* is due to three factors:

1. IT IS CLINICALLY PROVED.
2. IT IS EFFECTIVELY ENTERIC COATED.
3. IT IS DECIDEDLY LESS EXPENSIVE.

Indicated in treatment of coronary artery disease, edema and hypertension.

Dosage: One 7½-grain tablet four times a day, before meals and upon retiring.

Available on prescription in 7½-grain tablets, with or without Phenobarbital (½ grain), or 3¾-grain tablets, with or without Phenobarbital (¼ grain), and Theobromine Sodium Acetate 5 grs. with Potassium Iodide 2 grs. and Phenobarbital ¼ gr., 100 per bottle.

* Capsules are now available for those few patients who need extra medication.

CLINICAL VALUE OF MUSCLE EXTRACT

Carnacton *in*

ANGINA PECTORIS ARTERIOSCLEROSIS OBLITERATIVE ARTERIAL DISEASES

Carnacton is a biologically tested extract of *diaphragm muscle* — a powerful, markedly vascularized muscle with a high metabolic rate — most effective for its purpose. Carnacton is not only a vasodilator but also promotes cardiovascular tone and vigor.

In 1 cc. and 2 cc. ampuls — boxes of 12 and 50; vials of 30 cc. for oral use. Send for professional brochure.

CAVENDISH PHARMACEUTICAL CORP., 25 West Broadway, New York

MAJOR SOURCE OF BONE-BUILDING CALCIUM . . .

In the case of the young child, the usual diet, exclusive of milk, contains approximately 0.2 Gm. of calcium, while the diet of the older child contains approximately 0.3 Gm. The remainder of the daily requirement of 1 to 1.5 Gm. is usually supplied by milk. Thus one may speak of the milk requirement in relationship to the calcium need.

HORLICK'S FORTIFIED

prepared with milk, provides an agreeable, daily source of food calcium, and, in addition, presents the biologically complete proteins of milk plus a recognized daily minimum requirement of Vitamins A, B₁, D and more than 50% of G.

For Cleansing Soap-Sensitive Skins **ACIDOLATE**

TRADE MARK REG. U. S. PAT. OFF.

PROVIDES the thorough cleansing properties of selected sulfated vegetable oils—in combination with a non-irritating mineral oil which lessens any tendency toward skin dryness.

Acidolate is completely soluble in water. It can be quickly washed from hair or skin surfaces. Skin cleansed with Acidolate is left with a feeling of soft coolness.

The usefulness of Acidolate as an aid in the management or prevention of skin irritations has been demonstrated by properly controlled clinical tests.*

Complete literature will be sent to doctors on request.

NOW!

A Revolutionary Development in Intranasal Sulfonamide Therapy

PAREDINE-SULFATHIAZOLE SUSPENSION combines, for the first time, in a single stable preparation the effective vasoconstriction of 'Paredrine'* and the potent bacteriostatic action of sulfathiazole.

This preparation owes its remarkable effectiveness largely to the newly-developed 'Microform'* crystals—*approximately 1/1000 the mass of ordinary sulfathiazole crystals*. These crystals—pictured at lower right—form a suspension which: (1) approximates a solution in its ease of application... (2) deposits the sulfathiazole uniformly... (3) passes freely through the ostia of the sinuses.

Therefore, Paredrine-Sulfathiazole Suspension represents a revolutionary development in the treatment of nasal and sinus infections, particularly those secondary to the common cold.

MERCK

CONTRIBUTIONS

IN THE
VITAMIN
FIELD

EVER SINCE Ascorbic Acid was synthesized in 1934, the name Merck has been identified with leadership in the synthesis, development, and production of pure vitamins.

In 1936, Thiamine Hydrochloride was synthesized in the Merck Research Laboratories, and this achievement was followed, in 1938, by the chemical identification and synthesis of Alpha-Tocopherol by Merck chemists and their collaborators in other laboratories. In 1939, Pyridoxine Hydrochloride was synthesized in the Merck Research Laboratories, and in 1940 Merck chemists and their collaborators succeeded in identifying and synthesizing Pantothenic Acid.

Thiamine Hydrochloride, Riboflavin, Nicotinic Acid, Nicotinamide, Pyridoxine Hydrochloride, Calcium Pantothenate Dextrorotatory, Ascorbic Acid, Alpha-Tocopherol, Vitamin K₁, and Menadione are all being produced in commercial quantities in the Merck factories.

DISCOVERIES and advances in the vitamin field made by Merck chemists and their collaborators indicate the leading rôle played by Merck & Co., Inc., as manufacturer of these therapeutically important substances.

Merck & Co., Inc., manufactures all of the vitamins which are now commercially available in pure form, with the exception of vitamins A and D. Literature on the vitamins mentioned above will be mailed on request.

Ambulant Therapy in **Contact Dermatoses**

Through the use of Calmitol, absenteeism due to industrial dermatosis and contact dermatitis can be sharply reduced. Specific in an antipruritic action, Calmitol stops itching quickly; a single application is usually effective for hours. When applied to the lesion under treatment, it instantly brings relief from the discomfort. Scratching is thus prevented and secondary traumatic lesions are not produced. In most cases, relief is so great that workers are able to remain ambulant, and apply the medication themselves during rest periods. Through its protective influence, Calmitol enhances the efficacy of other indicated treatment. Physicians are invited to send for samples.

THOS. LEEMING & CO., INC. • 101 W. 31st St., New York, N. Y.

CALMITOL
THE DEPENDABLE ANTI-PRURITIC

Calmitol exerts its anti-pruritic influence by blocking cutaneous receptor organs and nerve endings. Its active ingredients are chlor-iodo-camphoric aldehyde, levo-hyosine oleinate, and menthol, incorporated in an alcohol-chloroform-ether vehicle. Calmitol is protective, bacteriostatic, and induces mild active hyperemia which aids in disposal of toxins.

the old
VARIABLE DOSAGE

In the past, Iodides in liquid form were assumed to furnish 1 grain of Potassium Iodide in a drop—but drops vary in size and even the solution might vary as much as 30 grains in an ounce. Today, you can be certain of the correct dosage with ENKIDE (Brewer) 15 grain Enteric Coated tablets of Potassium Iodide.

The Moving Finger Writes OF MORE NORMAL, HAPPIER PEOPLE

THE oscillating "finger" of the electroencephalograph, recording abatement of abnormality of brain waves, tells but a part of the story of epilepsy treatment with Dilantin[†] Sodium. Fewer and less severe seizures, more normal social and economic life have been observed in many thousands of epileptic patients receiving this modern anticonvulsant.

Dilantin Sodium possesses "many advantages" in the control of epileptic convulsions.¹ For one thing it is, in many cases, superior in anticonvulsant effectiveness to phenobarbital or bromides, and—highly important—it is practically non-hypnotic. The inclusion of Dilantin Sodium (diphenylhydantoin sodium) in the new U.S.P. XII speaks volumes for its therapeutic importance.

Annual Meeting

The 1943 Annual Meeting of the Medical Society of the State of New York will be held in Buffalo, May 3-6, 1943, at the Hotel Statler. It will be the second such meeting in wartime and should be attended by all who can possibly be there; yes, and even by those who for some reason think they can't! We know it will be difficult—use of cars restricted, train travel onerous, bicycles rationed, too far to walk, limited hitching and stable facilities for horses, too expensive to fly, canal boats and barges not running on regular schedules. Conditions were worse in grandfather's day, but he came in large numbers, and so will you.

Much has happened since we met in New York last spring, much that you will want to hear about: war medicine and surgery, new treatments, new instruments, changes in methods of practice, what the profession in various parts of the state and elsewhere is doing and planning to meet its particular needs. Invitations to attend have been

sent to the membership of the societies of neighboring states so that for the first time this year you will have the opportunity to meet those of our neighbors who can come. In a way, it promises to be rather a regional meeting, for some of the adjacent states have canceled their meetings or planned them at a different time of year or are holding them too far away. So you will see men and women from Pennsylvania, Ohio, Michigan, New Jersey, and possibly even Canada, as well as from the Empire State.

Make your plans now to come. Our exhibitors are putting forth a special effort in spite of transportation difficulties to show you what is new and how the old can be made to do. Later we shall tell you more of the scientific program, but just now we ask you to note the dates and to lay your plans to come. Buffalo, May 3-6, 1943—write it down *now* in your engagement book, then watch the JOURNAL for further announcements.

War and Social Reform, III

On January 6, 1943, Governor Dewey said, significantly, in his inaugural address: "In a rapidly changing industrial society, dislocation and reabsorption of workers is a continuous process. A broad and adequate social security program is required not only as an immediate measure but as a long-range policy." He said further, "The present

systems of unemployment insurance, workmen's compensation, relief, and welfare measures are now a patchwork. They must be integrated and broadened to provide increased service, including medical protection of the health of our people." He also recognized the increasingly grave problems of child welfare and their corollaries of juvenile

delinquency and a high crime rate, together with the difficulties being encountered by the state's mental hygiene institutions in the maintenance of proper care and supervision of their 90,000 inmates.*

In all of these problems the medical profession of the state has a vital interest. It is apparent that medical service, and especially the character and quality of medical service, is involved in every one of them. It is significant that broadening of the social security program to cover the human race "from the cradle to the grave" is become the new remedy, both state and national. We urge its intelligent use—while it still cures. And by "intelligent use" we mean so much broadening of the program as can be demonstrated to be necessary to meet an actual, not a putative or a propaganda-built need, and only so much as can be made to work practically. "Medical protection of the health of our people" might well be advanced by a greater integration of unemployment insurance, workmen's compensation, relief, and welfare measures. Much careful study seems necessary. We would not wholly agree that programs in these departments are patchwork. It is true that they have been developed through the years to a certain extent independently of one another, but at least as far as medicine is concerned there has been free and frequent consultation between the profession and state officials, with the result that in so far as the various programs have necessitated medical service, this has been furnished in a manner both realistic and practical.

This is not to say that improvement cannot be had by better integration. As a matter of fact, conditions brought about by the war make such improved integration all but imperative in the light of dwindling personnel, increased tax burdens, shortages of essential materials, and labor scarcity.

* **EDITOR'S NOTE:** See also the 1943 program of the Democratic Party as laid down by the late Governor Poletti (New York Times, December 30, 1942, page 1) which includes a "health insurance" plan financed by a payroll tax with employers, employees, and government all contributing, and, further, includes the cost of preventive medicine, hospitalization, and an income for the sickness period. It calls also for a \$10,000,000 program of child care for the 100,000 women of the state who are workers in industry.

We need, if medicine is to fulfill its part, as Dr. George W. Cottis has pointed out, more hospitals for the care of cancer patients, more convalescent homes to relieve the pressure on hospitals, extension of laboratory facilities, provision of diagnostic clinics in general medicine, more district or county health units.¹ These are the tools with which modern medicine works and without which it cannot reasonably be expected to improve or to expand its services to the public. Either ways must be found within the state to provide and assure these essentials or the "medical protection of the health of our people" will not be fully realized.

Dr. Arthur F. Chace, its president, and the New York Academy of Medicine have faced the "responsibilities that must be faced by medicine at a time when health and morale are inseparable."² In his inaugural address, Dr. Chace takes cognizance of post-war problems as well as immediate needs. He opens a way by which medicine with the resources that the Academy and other medical societies have available can lead the way in the study of social medical problems, of medical education, the effect of nutrition and the occupational environment on masses of people, the proper distribution of medical services, relocation of migrant populations, thus helping to lead the way for government and private initiative. Such research is badly needed. We must have the facts first, not generalizations; next, the facts must be scientifically interpreted and the actual needs ascertained. Those needs must then be fully and practically implemented by the public and private resources of the state.

The successful prosecution of a war or the effective evolution of social betterment is basically dependent upon the provision of modern, necessary, and well-planned equipment and methods. We must make better use of what we have, certainly; but, in addition, the state and the medical profession must plan together the expansion of medical service, the implementation of the medical aspects of proposed plans if these plans are to be laid within the framework of reality and thus be reasonably workable.

¹ New York State J. Med. 43: 26 (Jan. 1) 1943.

² New York Times, Jan. 8, 1943, p. 18.

Rational Rationing

One of the impressions gained by reading the testimony given before a subcommittee of the U.S. Senate Committee on Education and Labor, of which Senator Claude Pepper is chairman, as reported in the *J.A.M.A.*,* is that the numerical distribution of physicians with respect to population is the important thing in the maintenance of the public health, as far as government is concerned.

We concede that it is important, but it is not the whole story. The modern physician, both urban and rural, depends for his effectiveness upon hospitals, transport, electric power, and the willingness of the people in the area he serves to accept his services. Whether the question is one of bringing the physician to the people or group of people, or the people to the physician or group of physicians, communications are of primary importance. Living conditions, especially in winter, may be of the utmost significance with respect to the amount of disease occurring in a given area. Bungled rationing with respect to gasoline, tires, fuel oil, or power could materially alter the medical efficiency of physicians in a given area no matter what the numerical physician-to-population ratio might be. Similarly, a fuel oil and power shortage in another area might so suddenly increase the amount and severity of disease, so impair the efficiency of hospital operation that the physicians and hospitals, though numerically correct with respect to medical exponents and hospital beds in relation to population, might be unable to cope with the situation.

It would seem to us that to date no one has paid particular attention to the vital matter of medical effectiveness, which seems likely to become a larger problem as rationing becomes—as it must—more severe and more inclusive. We urge that it be not overlooked in the present concentration of thought on the matter of mere physician distribution. It is to be kept in mind also that as more and more of the young men go

into the armed services, the care of the civilian population will be carried on largely by the group of men 45 years of age and over. In the age group of 65 and over a "bare 30 per cent" are effective for all purposes; in the group of 45 to 54 there are 31,399 physicians; in the group of 55 to 65, 30,000 physicians. What could be considered the effectiveness of this group, 45 to 65, comprising 61,399 medical men? Examination of the men for the armed services showed a rapid increase in the number of physical defects for each decade. What significance has this fact when related to the effectiveness of this 45 to 65 age group?

There is no doubt that a physical examination of this group (45 to 65) would show a rapid decline in energy available for civilian population care with each additional decade above 45.

How will this affect the plans for distribution? Is one doctor per 1,500 of population sufficient regardless of the level of the physician group health in that area? What is the level of the physician group health in any given area? Does any one know? We doubt it.

These 61,399 physicians must last out the duration; there seems to be little prospect of increasing their number. Will we be as wasteful of our physician stock pile as we were of our rubber? As heedless of conservation until it is too late? There can be no synthetic physicians, remember. Isn't it about time we took stock of the group health of the 45 to 65 age group? Isn't it time now to see to it that every facility, for transport especially, and for maximum effectiveness of operation and practice be assured to this small group upon whom rests the responsibility for the national health? Wise planning can effect much benefit; tinkering with a system of medical practice in the middle of a war could be disastrous.

This is no time to be content with patchwork. Rational rationing and national planning are called for; let us have them, and let them be practical.

* *J.A.M.A.* 120: 927 ff. (Nov. 21) 1942.

Ulcerative Colitis—A Problem

Although they may offer no immediate threat to life, some diseases, by their protracted course, often cyclic, and by their meager therapeutic response, are disheartening to both patient and doctor. Such a disease is nonspecific, ulcerative colitis,¹ which by its very terminology indicates *its cause is still unknown*. Search for causative micro-organisms, parasites, and viruses² has yielded no generally accepted etiology. Inevitably allergic³ and psychiatric components⁴ have been suspected as primary agents. Experimentally, in dogs, obstruction of the lymphatic drainage of the ileocecal segment of the intestine has produced ulcerated lesions aggravated by the injection of nonpathogenic bacteria.⁵ When the causative agent is unknown, it is difficult to institute effective rational treatment.

Dietary treatment, stressing water, mineral, vitamin, and protein needs, while invaluable, is supportive but not curative. Chemotherapy, with the discovery of sulfaguanidine and sulfasuxidine, gave rise to great hopes only to lead to final disappointment.⁶ Various parenteral therapies and rectal irrigations have simply served to increase the number of agents tried in this disease. In addition, the ultimate mortality from ulcerative colitis is about 20 per cent.^{1,7} With few exceptions, the survivors suffer from poor health and are unable to perform their normal tasks.

Revelation of this unhappy state of affairs led enterprising surgeons to conceive the idea not of a desperate, last-stand ileostomy, but of resection of the involved colon. Obviously, operation is performed only after a careful medical study has eliminated the factors of allergy and infection, local and focal, and after a meticulous

dietary regimen has failed. Nutritional deficiencies, anemia, and faulty metabolism are corrected preoperatively. Operative indications and different technics for this procedure, as well as postoperative care, have been scrupulously detailed.^{1,7}

The published results of such operations seem to be an improvement over those of prolonged medical treatment. The mortality at present is no greater with surgical than with medical care. The great difference is the restoration to health and functional efficiency of the majority surviving the colectomy. Studies of colectomized patients have demonstrated that after an interval of about three months the functions of the lost colon are assumed by the dilated lower ileum, and the absorption of water and minerals, while not quite normal, becomes adequate.

No claim is made that this is the ideal cure, for a permanent ileostomy is never an object of pleasant contemplation. It is preferable, however, to the gradual deterioration of the unfortunate patient into a state of hopeless invalidism. Final judgment should be passed only after conference among the internist, gastro-enterologist, and surgeon, all expert in the intricacies of this problem. Ulcerative colitis is still a challenge to the medical profession.

Correspondence

Therapeutic Abortion

To the Editor:

There are records of cases in which the Judiciary were unable to prosecute an alleged criminal abortionist because of the lack of knowledge or the indefinite wording of the present law. The existing phrase "to save a life" has a great deal of latitude. In the interest of the public and profession, a more detailed explanation of a therapeutic abortion should be made. With the progress medicine has made in the management of certain diseases, the indications for interruption of pregnancy are certainly fewer. It is, therefore, the aim of the writer to have introduced in the legislature a bill which provides a more specific definition of "therapeutic abortion."

Therapeutic abortion is the artificial interruption of pregnancy before the period of viability is reached. It is done only for those conditions in which the

continuance of pregnancy jeopardizes the life of the mother or aggravates the disease from which she suffers.

The treatment of many of the conditions which formerly were aggravated by pregnancy has been improved so much that they are now treated satisfactorily without interfering with the gestation. Therapeutic abortion, accordingly, is rarely justifiable. When it is indicated the operation should be performed in an approved hospital with all the precautions of a major surgical procedure, and the written opinion of two competent, qualified, and recognized consultants in the respective specialties should be incorporated in the hospital records.

Forum on Therapy of Wartime Injuries

AT THE annual meeting of the Seventh District Branch of the Medical Society of the State of New York, held at Rochester on September 23, 1942, there was staged a forum on "Therapy of Wartime Injuries." Dr. Leo F. Simpson, member of the Emergency Medical Advisory Committee in charge of surgery, acted as interlocutor.

—Editor

BLOOD, BLOOD PLASMA, AND BLOOD SUBSTITUTES

JOE W. HOWLAND, M.D., Rochester, New York

IN THE past few years great advances have been made in the therapy of war injuries, especially those that are due to hemorrhage, trauma, and burns. The most important of these newer procedures is in all probability the controlled transfusion of blood plasma and whole blood. By careful observation of the patient and his response to this type of therapy, an adequate blood volume can be maintained, hemoconcentration and tissue anoxia prevented, and shock either brought under control or averted. With this knowledge, the medical commissions of the Army, Navy, and Office of Civilian Defense have requested enormous amounts of blood plasma. The Blood Procurement Units of the Red Cross here and elsewhere have undertaken to meet this demand, and in the past year the Rochester Unit alone has donated some 38,000 units (equivalent to 38,000 pints of whole blood), for which they must be highly commended. The Red Cross Blood Procurement obtains the blood and delivers it for drying to large pharmaceutical houses under contract to the Army and Navy. The entire project is directly under control of the National Research Council through the National Institute of Health.

It is obviously impossible to review the tremendous amount of theoretic and practical knowledge on this subject in a short article. An attempt will be made to discuss whole blood and plasma from a practical viewpoint, with specific emphasis on the indications for use, methods of preparation, mode and control of administration, reactions, and methods of storage.

Whole Blood

1. INDICATIONS FOR USE

(a) *Replacement of Erythrocytes.*—Whole blood is used when it is necessary to replace erythrocytes, whether they be lost by hemorrhage, hemolysis, or failure of erythropoiesis. Hemorrhage is perhaps the most common of severe traumatic

injuries, and the most satisfactory treatment of it is the immediate transfusion of whole blood. Blood plasma may be used, but the number of available cells which can be removed from the erythrocyte pools in spleen and red marrow is inadequate. Hence, plasma can be used, but early transfusion of additional cells in the form of whole blood is the correct procedure, especially when large amounts of blood are lost.

(b) *Treatment of Burns in Late Stages.*—After the initial shocking phase of treatment is over, whole blood is usually necessary because of red cell destruction.

(c) *Treatment of Infection.*—Whole blood is particularly valuable in cases in which hemolytic organisms are well established.

(d) *Prothrombin Deficiencies.*—Control of deficiencies can be brought about by the use of fresh whole blood or plasma transfusion with elevation of the level toward the normal.

(e) *Treatment of Carbon Monoxide Poisoning.*—The fixation of carbon monoxide as CO-hemoglobin makes it useless as an agent for oxygen transport and also brings on massive hemolysis if recovery with oxygen is delayed or slow. Transfusion of new blood is an essential part of the treatment in severe cases.

(f) *Treatment of Hemorrhagic Diatheses.*—It is indicated in the treatment of hemorrhagic diathesis, particularly the purpuras and hemophilias. Hemorrhagic tendencies can be reduced and even controlled by the use of whole blood. The result is usually transitory. Reactions to whole blood may be severe in these cases.

2. DISADVANTAGES

- (a) Typing and cross-matching are necessary.
- (b) Reactions are more severe, and the reaction rate is higher.
- (c) The problem of storage and transport must be solved.

3. CONTRAINDICATIONS

- (a) Cardiac decompensation or known severe cardiac damage.
- (b) Cases of shock with marked hemoconcentration.

Read as a part of a symposium at the Seventh District Branch Meeting of the Medical Society of the State of New York, Rochester, New York, September 23, 1942.
From the University of Rochester School of Medicine and Dentistry, Rochester, N.Y.

4. METHODS OF PREPARATION AND USE

Very little discussion will be given on this familiar procedure. The careful typing and cross-matching of the blood of donor and recipient are necessary. The procedure of choice for these is the test tube agglutination at 37 F. for 30 minutes, approved by Landsteiner, Weiner, and Levine.

(a) *Direct Transfusion.*—Sterile precautions, requiring the use of syringes or an apparatus such as that devised by DeBakey, must be followed in direct transfusions. The blood is taken from the donor and immediately given to the recipient. If reactions are thought to be caused by the anticoagulant, this procedure may prove useful. For the apparatus method, heparin is usually necessary before an adequate amount of blood can be transfused.

(b) *Indirect Transfusion.*—In giving an indirect transfusion, the blood is put, again under sterile precautions, into a solution containing anticoagulants in varying concentrations. If blood is to be used within forty-eight hours, the standard 50 cc. of 5 per cent sodium citrate is adequate (or 100 cc. of 2½ per cent sodium citrate). If it is to be stored for varying periods of time, the glucose citrate (Rous-Turner) mixtures of either DeGowin or Elsever and Ainslee are satisfactory. In these mixtures, approximately equal volumes of anticoagulant and blood are used, giving a half-dilution of cells and plasma. If the supernatant plasma is later taken off, it will have only half the protein per unit volume. With the glucose-citrate mixtures, blood can be safely stored from ten to thirty days without appreciable increase in reactions.

5. ADMINISTRATION

In administration of whole blood, certain precautions should be taken. The blood should be given as taken from the storage refrigerator and should never be heated. Severe and even fatal reactions have been caused by heating whole blood. After passing through the tube of the recipient set, the blood will be sufficiently warmed for injection.

The patient should be under close observation during transfusions so that in case of a reaction the flow can be stopped and the necessary therapy instituted.

Blood should be transfused slowly. A drip indicator forms a useful guide for the rate of flow.

Adrenalin in 1:1,000 solution should be instantly available in case of a transfusion reaction.

6. REACTIONS

(a) *Pyrogenic* reaction may come during or immediately after the transfusion. Symptoms are a chill followed by fever of 101 to 103 F. persisting from two to six hours and subsiding spontaneously. These are caused by poorly cleaned

equipment containing various bacterial and protein breakdown products. The treatment can be summarized as none if mild; discontinue transfusion if severe.

(b) *Urticarial* reaction is a development of urticaria varying from a few wheals to generalized angioneurotic edema. The cause is unknown. They subside in from six to twenty-four hours and respond immediately to subcutaneous adrenalin.

(c) *Hemolytic* reactions are the most severe and are thought to be due to breakdown of red cells and packing of the kidney tubules with hemoglobin crystals. They occur following transfusion of incompatible blood. The symptoms are constriction of the chest, substernal pain, and dyspnea followed by chills, fever, and pain in the lumbar region. Later a shock state develops, with dyspnea and air hunger. Anuria occurs finally and is due to the packing of the kidney tubules with hemoglobin. These reactions may develop even after a very small amount of blood is transfused. No treatment is necessary in the absence of shock or anuria. Plasma may be necessary to combat the shock. The urine should be alkalized as rapidly as possible in order to dissolve the hemoglobin crystals.

(d) *Circulatory* reaction brings such symptoms as dyspnea, cyanosis, and the appearance of the early signs of pulmonary edema in chest examination. This effect is due to the overbalancing of the circulation by the introduction of added blood into the venous return. The treatment is phlebotomy and frequent venous stasis by the tourniquet.

(e) *Retinal hemorrhage* occasionally follows transfusion, with all the typical symptoms and signs. It is quite common in patients with blood dyscrasias. No treatment is prescribed.

(f) *Transmission of infection* occurs occasionally after transfusion, malaria being quite common. Oftentimes the organism may be dormant in the donor but induces the disease in the recipient. Syphilis may also be transmitted, especially when blood from the seronegative early case is given.

7. THE BLOOD BANK

Little comment is necessary on the functions of a blood bank. The majority of them are operated on a barter system with replacement of the blood used at an opportune time. Its great advantage lies in the availability of typed whole blood in the case of an emergency. It has value in fixed locations, but for a mobile group such as an army unit or a ship whole blood is rendered quite unsatisfactory because of its great bulk and its tendency toward hemolysis with constant movement. The problem of refrigeration presents

further difficulties, of course. Using the glucose-citrate solutions, it is possible to store blood for as long as fifteen days without appreciable rise in the incidence of reactions.

In the so-called blood and plasma bank, ordinary citrate anticoagulant is used, and if blood has not been used within forty-eight to seventy-two hours, it is centrifuged and the plasma removed with sterile precautions. The latter procedure will be discussed later in this paper.

In acute emergencies when time is an important factor, plasma has been the treatment of choice. In field emergencies with no laboratory facilities available, it is impossible to give whole blood safely. Some have suggested the use of all type O (IV) blood. However, in cases sufficiently injured to demand blood to that extent, the likelihood of reactions is also increased, and we do not recommend this procedure. Methods are available in which cross-matching can be done rapidly although these are by no means as satisfactory as the routine test-tube procedure.

Blood Plasma

1. INDICATIONS FOR USE

(a) *Shock*, if caused by hemorrhage, may be treated with plasma until whole blood can be obtained. In trauma and burns, it should be used in normal or half-concentration to support the blood volume and to prevent hemoconcentration. This treatment must be followed by hematocrit and specific gravity determinations for adequate control.

(b) *Hypoproteinemia*, whether it be due to inanition (high intestinal obstruction, etc.), faulty absorption of proteins (cirrhosis or infection), or excretion (nephritis, cirrhosis), may be treated by large plasma injections. This assures only a temporary benefit and then only by utilization of large amounts of plasma. The indication for plasma in such states is only to tide the individual over an acute emergency until synthesis of new protein can be resumed. Hence, it would be useless in chronic nephritis, cirrhosis, and the like. Experimental evidence confirms this supposition.

(c) *Hemorrhagic diatheses* will respond to plasma in a manner similar to that in which they respond to blood.

(d) *Diuretic action* may be obtained by the use of concentrated plasma in certain cardiac conditions and in nephritis when the accumulation of edema fluid is related to a relative hypoproteinemia and an increased blood volume. In such cases one should be very careful about the speed of injection of the hypertonic solution, as the blood volume may increase to such an extent as to cause cardiac failure.

(e) *Infections and toxemias* derive a definite benefit from the use of fresh plasma. The nature of the action is not known.

(f) *Immune bodies*.—The established benefit of plasma or serum in the prophylaxis and treatment of infectious disease is well known. The use in measles is a typical example.

2. ADVANTAGES OF PLASMA

(a) Requires no typing or cross-matching.

(b) May be preserved for long periods of time by freezing or by freezing and drying.

(c) Easily transported and stored.

3. TYPES OF PLASMA AND THEIR PREPARATION

(a) *Wet plasma* is prepared by the centrifugation of seronegative citrated whole blood and by removing the supernatant plasma. The plasmas from 8 to 10 donors are mixed in a large flask, this procedure or "pooling" tending to reduce the likelihood of transfusion reactions which might be caused by a high agglutinin titer in a single plasma. A measured amount of bacteriostatic agent, such as methiolate or phenyl mercuric nitrate, is added to each pool as a precautionary measure. This pooled plasma is then cultured for sterility and placed in 450 cc. bottles, 250 cc. being allotted to each. The amount of plasma in a single bottle is called a unit. These are then stored as wet plasma or frozen and are not to be used until cultures for aerobic and anaerobic organisms have been pronounced negative.

(b) *Frozen plasma* is prepared from wet plasma by freezing it in a bath or freezing compartment at a temperature of -30°C . or lower. After such freezing, it may be kept indefinitely without deterioration. Frozen plasma is easily and rapidly thawed in a water bath at 37°C . If allowed to stand at room temperature, a turbidity of the solution results. The time required to melt the plasma is from fifteen to thirty minutes. After thawing, the plasma may be refrozen without damage or denaturation of the protein.

(c) *Dried plasma* may be prepared in a number of ways, only one of which is approved, however, by the National Institute of Health. The accepted process, now being used almost exclusively for the drying of plasma for the Army, Navy, and Civilian Defense, is that of drying from the frozen state, a process known by the copyrighted name, "lyophile." "Desiccated or dried plasma" is the appropriate term for it.

The sterile pooled plasma is frozen very rapidly in a layer of uniform thickness in the standard plasma bottle (450 cc.). This is accomplished by revolving this bottle on its long axis in a bath of alcohol at approximately -65°C . Thus is formed a cylinder of frozen plasma with a wall of uniform thickness from which evaporation will take

place at a constant, steady rate. Covered with a gauze mesh, these bottles are placed in the drying chamber of the apparatus, which is then closed with a vacuum-tight seal. The chamber is evacuated down to a residual pressure of about 0.1 to 0.3 mm. Hg by the use of a mechanical pump. This low pressure is sufficient to keep the plasma frozen by evaporation of moisture from its surface. Next, heat is applied to the drying chamber in order to increase the rate at which the moisture passes off the layer of frozen plasma. The moisture is swept out of the bottles through a tube leading to the pump and is condensed from the system by refreezing against a very cold cylinder immersed in a bath of alcohol at -65°C . This process is continuous until the plasma is dried, a period of forty to sixty hours usually being required.

After the drying is completed, the plasma is then capped and its residual water content (usually less than 1 per cent) is measured; then a pilot bottle is reconstituted by addition of sterile water agitating to complete solution, and aerobic and anaerobic cultures are taken. A determination of the hemoglobin and protein content is made, and if the cultures are negative, it is released for use.

All the above plasmas can be used as normal and half-dilution plasmas. For half-dilution, an equal quantity of saline is added to the plasma. For normal plasma, in the case of the dried product, the original volume of solution (250 cc.) is added. In making concentrated plasma, one quarter of the original volume of distilled water is usually added to the dried plasma and placed in the solution.

4. ADMINISTRATION

The technic of administration is similar to that of whole blood except that the special Army-Navy-Civilian Defense setup is used. All plasma supplied by our laboratory will be furnished in these containers.

Necessary precautions in giving plasma are as follows:

- (a) Do not heat plasma above 37°C .
- (b) Inject plasma slowly, preferably with the use of a drip indicator. This is especially true of the hypertonic concentrated plasma which, by its marked osmotic effect, can cause precipitous rises in venous pressure.
- (c) Dried plasma should not be dissolved in Ringer's solution, as the excess calcium ion may induce spontaneous clotting.
- (d) Plasma showing extensive hemolysis should be discarded.
- (e) Transfusions of whole blood should not be given immediately after large amounts of plasma. There may be a troublesome rise in circulating

agglutinin titer of the plasma. This persists for as long as twenty-four hours in some cases. If blood is absolutely necessary, use the universal donor (type O-IV) after a cross-match of a careful nature.

(f) Do not give concentrated plasma in shock or burns, for it will have little or no effect and may even be deleterious.

5. REACTIONS

Reactions from plasma are similar in nature to those noted in whole blood transfusion. In our experience they have been much less severe.

6. THE PLASMA BANK

Many of the particulars concerning the plasma bank were discussed in the section on whole blood. Plasma may be stored in the three ways mentioned in connection with the preparation of whole blood.

If plasma is stored as wet plasma, a precipitate begins to form after about seven to ten days and gradually settles to the bottom, making the solution turbid. This does not prevent its use, but it may increase the likelihood of reactions. Hence plasma may be kept for about three to five days as wet plasma, after which, in our opinion, it should be frozen for further storage.

Frozen plasma must be stored at approximately -20°C . or less and will keep indefinitely in a cabinet at this temperature. This plasma must be thawed at 37°C . before use.

After drying, plasma will keep indefinitely at room temperature, providing that the moisture content is kept low. This may be done in several ways. The best process is to seal it in vacuum cans, as is done for the Army and Navy. The other is to cover the sterile rubber stoppers with plastic caps, thus excluding the air from the evacuated interior. To use such plasma the caps need only to be removed and water added according to directions found in the package. We do not know how long such plasma will remain good but certainly for a long period of time.

Blood Substitutes

No review of the therapeutic application of blood and plasma is complete without a brief account of the present status of the so-called blood substitutes. This includes the heterologous plasmas such as beef, the purified albumins and hemoglobin, digests and hydrolysates of proteins, and biologically foreign materials such as acacia, pectin, and gelatin.

For a little more than a year attempts have been made to use heterologous plasmas in the treatment of shock states. The results have been favorable in the immediate benefit of the shocked patient, but the per cent of reactions is very

high—20 per cent or more, with many being very severe. The incidence of reactions to a repeat dose is also high. Serum disease is common, as well as a persisting sensitivity to the foreign plasma.

Purified human albumin is being made from plasma that is contaminated, hemolyzed, or otherwise unsatisfactory for processing. The albumin is purified by a process of differential denaturation of protein with complete removal of the globulin fraction. The final product is concentrated (about 30 per cent protein) and has a high osmotic effect. The reaction percentage is relatively low. Clinical and experimental evidence at the present time, however, indicates that although an adequate blood volume can be maintained or even increased by mobilization of body water, the therapeutic efficiency is not as high as that of plasma. The explanation of this is not understood.

Purified beef albumin has been prepared in the same way. Its incidence of immediate reactions is low, but sensitivity and serum disease have been caused by this agent. The therapeutic effect is probably identical with that produced by the human albumin.

Although purified hemoglobin with a high immediate osmotic effect has been prepared, its low renal threshold prevents retention with excretion into the urine in massive quantities. This in the presence of an acid urine causes precipitation of the crystals in the kidneys and a resulting anuria which may prove fatal.

Digests and hydrolysates (enzymatic, acid, and alkaline) of casein, beef serum, and the like are now manufactured by many recognized pharmaceutical houses. They are useless in immediate emergencies, as for example, in the treatment of hemorrhage, trauma, or burns, but they are useful for parenteral feeding when food cannot be taken by the oral route. Reactions to these substances are moderately common.

Acacia in a 6 per cent solution is probably the most familiar of the blood substitutes and is universally used. It has, however, been the contributing cause of many fatalities, usually when used repeatedly over a long period of time. The deposition of the acacia in the liver parenchyma causes a breakdown of functioning liver cells, and if this takes place to a great degree, the outcome may be death from hepatic insufficiency. If used in the absence of blood plasma or blood, it should not be continued for a prolonged period.

Pectin and gelatin are the newest members of the family and are still in the experimental stage. Reactions are not uncommon and may be severe. The process of elimination of these substances is not well understood. Since this work was started, sufficient time has not elapsed to deter-

mine the latent effects of these substances when used in therapeutic amounts.

Present Status of Blood and Plasma Procurement for Civilian Defense in Monroe County

A short time ago the committee for blood and plasma procurement met to consider the problem of procurement in case of an emergency. All hospitals in Rochester were represented. At that time, because of the variety of methods of preparation and equipment in the individual institutions, it was felt that if small numbers of casualties were allocated to each hospital, the existing facilities would be adequate. It was also decided that the larger plasma bank at the Strong Memorial Hospital could furnish extra plasma to the other institutions up to a limited amount. Approximately 500 units of emergency plasma were established as the minimum amount necessary to take care of a small emergency in this area.

Since that time, through the cooperation of Dr. Arthur Johnson, head of the Health Bureau, Dr. Basil MacLean of Strong Memorial Hospital, and the Office of Civilian Defense Blood Procurement Group, equipment for the preparation of some 2,500 units of dried plasma for use in this area has been ordered. Much of this equipment is now on hand in spite of the difficulty with priorities, and some of the plasma is now dried and ready for use. Special kits have been designed and are on hand to simplify the procedure for those unfamiliar with the administration of plasma. Some of the funds for this project were furnished by the Office of Civilian Defense for purchase of equipment, and we are indebted to the Rochester Chapter of the Benevolent Protective Order of the Elks for funds to build the drying apparatus used in this project.

Through the cooperation of the Office of Civilian Defense an additional 500 units of frozen plasma with a storage refrigerator have been sent to this area and will be used in case of need.

Should an acute emergency arise, the Local Blood Procurement of the Red Cross would be able to furnish whole blood in the necessary amounts. This organization tentatively plans to release a weekly quota from its total bleedings to the plasma bank at the Strong Memorial Hospital for drying and storage. This will provide the plasma for the 2,500 units as described previously. The entire project for Civilian Defense is under the direct control of Dr. Fred A. Bryan, the regional technical adviser on blood procurement to the Office of Civilian Defense.

With this arrangement well on its way to completion, the City of Rochester and the Monroe County area should be well supplied with both plasma and blood in case of an emergency.

TREATMENT OF BURNS

JAMES S. HOUCK, M.D., Rochester, New York

THE problem put before the committee on the treatment of burns was that of adopting a routine that could be used to treat any number of patients at a given time. A disaster resulting from an act of war means many casualties. Each of the hospitals in Rochester can handle several cases of severe burns readily at any time, but with dozens, perhaps hundreds, flowing into their doors, how will they manage? Plans had to be shaped to meet this possibility, for it is distinctly not a question of how we would handle the individual case in civilian practice.

It is necessary that supplies be available in large amounts and that personnel be sufficient to care for a variable number. The City has designated fire houses as casualty units and is equipping these places with supplies. With a large number of depots such as these, it was important that the adopted routine be thoroughly standardized as simply and at the same time as effectively as possible. After a careful and deliberate survey of the accepted routines, it was concluded that despite the criticisms of tannic acid and silver nitrate, it met the requirements better, at least for the present, than the others. The statements that follow, therefore, are, in the judgment of this committee, representative of the details necessary to carry out this treatment satisfactorily.

In order that burn cases might be evacuated from the casualty stations rapidly, it was decided that *first aid only* be administered there—the minor burns constituting erythema of small areas to have sterile vaseline applied and a snug sterile bandage to cover the entire area. The severe burns should receive adequate morphine—that is, $\frac{1}{3}$ to $\frac{1}{2}$ grain. The clothes should not be removed, nor should any attempt be made to apply anything to the burned area. Chemotherapy was considered but rejected on the grounds that in the hurry of moving these patients large amounts might be administered and the subsequent danger of toxic symptoms from rapid absorption would make its use dangerous. The burn should be covered only with a sterile dressing, a blanket should be placed about the patient, and he should be transported to the hospital.

At the hospital the minor burns are treated as at the casualty station, making sure that moderate pressure is applied over the sterile

dressings. It is considered important to treat all severe burns of less than six hours' duration as traumatic wounds, so that under proper care they should heal without infection. It can be stated without reservation that the anchor sheets of all accepted treatments today are combating shock and preventing infection.

For practical purposes the details of treatment of both of the above factors should go along simultaneously as far as possible. More morphine should be administered if the pain is not controlled. Use of enough morphine should be stressed, as it lessens shock and makes it possible to carry out a large part of the necessary treatment. Generally, it is the belief of this committee that inhalation anesthesia should be avoided. The immediate danger here exists as a sequel to the inhalation of flames and poisonous gases. With the irritation thus established in the respiratory tract, the addition of inhalation anesthesia would only be adding insult to injury. The detailed instruction sheets circularized to the Civilian Defense staffs here have emphasized heavy sedation rather than anesthesia. Pentothal sodium or evipan, intravenously, would, in some cases, be necessary to carry out the more extensive forms of débridement. In the rare cases requiring deeper anesthesia, a skilled anesthetist should administer the preferred agent.

At this time arrangements for the administration of blood plasma at the casualty station have not been carried out. We believe that with the present transportation system these cases will be brought into the hospitals without delay, but should transportation facilities break down and plasma not be given, we know that our mortality figures would suffer. Prompt administration of blood plasma to all serious burns is *imperative*. No laboratory work is necessary before it is given; therefore, if delay occurs anywhere along the route, administration of it should be started. All severe cases should have plasma immediately after admission to the hospital in any event. This early use of plasma is, of course, to combat the primary fluid loss and shock. It should not be confused with the total amount necessary for the individual case.

When a burn occurs, it is sterile, or at least approximately so, and every effort should be made to keep it that way. All steps to prevent infection will be rewarded by simplifying the subsequent care in many ways. It is much

easier to prevent infection than it is to treat it later—to this I am sure we will heartily subscribe; therefore, care in promoting asepsis is essential. The initial steps having been accomplished, the surgeon prepares as for any surgical procedure—that is, scrubbing ten minutes, wearing sterile cap, mask, gown, and rubber gloves. All operating room personnel should wear cap, mask, and gown. The patient is brought to the operating room, or if one is not available, to a room having a controlled temperature of about 80 F., free from drafts and visitors. The clothes should be removed with sterile instruments. After this is completed, the surgeon should change his gown and gloves, then wash the burned area for ten minutes with sterile soap and soft gauze. It should be carefully débrided of hanging skin and all ivory-white dead tissue. It is very important that gentleness be exercised in all the above steps. Do not use a scrubbing brush, alcohol, or other strong solutions. Following cleansing and débridement, the area is rinsed thoroughly with sterile saline solution. The prepared field should be dried and then sprayed with tannic acid and silver nitrate solution, comprising a 10 per cent aqueous solution of each. The patient is placed in his bed on a sterile sheet, an electric cradle over him, covered by a sterile sheet. The temperature to be maintained beneath this cradle or tent should approximate 90 F. The above solutions should be applied by atomizer every half hour until such time as the eschar has taken on a light brown color, and then they should be stopped. It is useless to continue spraying further, as it results in a definite waste of time and causes a much thicker eschar than is necessary. The thick eschar is one of the pitfalls of this treatment. It is impossible to locate infection beneath a heavy crust. With the light crust the patient is more comfortable and infection is easily identified as a loose, puffy, compressible area. When these areas are encountered, they should be opened, treated locally until the infection is cleared, and then sprayed again with tannic acid and silver nitrate solution. The exceptions to the above tanning routine are that no eschar should be formed on the face, hands, or genitalia; sterile vaseline dressings should be used on these parts.

Early in Davidson's original investigations he focused attention on the fact that tannic acid kept the patient comfortable. He elaborated on the precipitation of protein in the burned tissue, thus inhibiting dehydration and minimizing toxic absorption. Certainly there is no doubt that it is a powerful agent in the prevention of infection. We find, therefore, that it fulfills

the basic factors of treatment—namely, shock and infection. It is relatively easy to obtain and lends itself to the mass treatment of casualties without vast accessory supplies or equipment.

Emphasis has been placed on the use of blood plasma in combating early shock; in the treatment of delayed shock it has no equal. The outpouring of vital fluids with the severely burned case is tremendous, and with this loss, shock becomes deeper. It calls for almost a continued intake of blood plasma to hold these patients from serious damage or even a quick fatal issue. At Pearl Harbor many of the burn fatalities were attributed to the lack of this essential fluid. It is, therefore, obvious that every effort directed toward increasing an available supply of blood plasma at casualty stations, and especially the hospitals, will save lives. Estimation of burned area, as advised by Berkow, helps greatly in anticipating the patients' further care and need for fluids. In general, it may be said that if 10 per cent of the body surface is burned, 1,000 cubic centimeters of blood plasma should be given. The amounts should be increased directly in proportion to the increase in percentage of burned field. It should be given intravenously over a twenty-four hour period in small divided doses. Saline and glucose may also be given, but not to exceed the amount of plasma given in the same period. It should be kept in mind that saline and glucose can be harmful. They should be used only as an emergency substitute for plasma. Edema occurs when saline and glucose alone are used. Hemoconcentration is not relieved because the necessary colloidal elements are lacking. The patient may be permitted to drink moderate amounts of fluid, but no food should be given by mouth until the stomach is retentive and shock is controlled. The hematocrit aids in determining what fluids are needed, but as a rule no special laboratory methods are indicated. The clinical evaluation should be, and is, the best guide. When hemorrhage occurs as a result of the burn or concurrently with it, whole blood transfusions should be given. They should also be given with the gradual anemia that develops with some severe burns.

In the event of lung involvement, however minimal, oxygen inhalation therapy should be started. A Boothby mask can be used and a concentration of at least 60 per cent oxygen should be attained. It not only aids in lowering the incidence of respiratory complications, but lessens anoxemia and decreases the degree of shock.

After a period of seven to ten days while the eschar is still clean it should be surgically removed. All third degree areas should be

grafted. The second degree areas should be dressed with sterile vaseline gauze and the usual pressure dressings used for grafted areas. This dressing should not be changed for ten to fourteen days unless fever or other signs demand it.

In conclusion, it is our belief that attention to details is the important issue. Even though

they may seem elementary in many instances, rigid completion of the steps as outlined results in quick relief and an early cure. No attempt has been made here to discuss the various splendid treatments or the plans of rehabilitation, for our chief concern is with the immediate care of a few or many casualties.

SHOCK

MAURICE A. BARNARD, M.D., Rochester, New York

SHOCK, always of interest to the surgeon, obstetrician, and physician, now becomes of interest to the first-aiders and the public. A committee of medical men from the Rochester hospitals has given serious study to this problem through the stimulus and direction of the medical defense committee. Dr. Don Hutchens was chairman of this committee in its study stage. He is now Major Hutchens with General Hospital No. 19. The report of his committee is presented herewith:

In the event of possible bombing of cities, the experience of the English medical personnel suggests the value of the practical rather than the theoretical import. As is well known, such casualties have a high mortality, and the living injured are badly hurt. The recognition of shock and its treatment at the site of the disaster are stressed in order to cut down the increased incidence of mortality in delay and the added trauma of handling and lost time. This places tremendous responsibility on the judgment and decision of the casualty station surgeon. It gives him the position of battalion surgeon in the army and demands quick decision and decisive, direct action. He must train himself and his personnel to avoid confusion under trying circumstances. Careful handling of these badly injured cases is necessary, and sometimes treatment of shock, such as plasma infusion at the site before transfer, may be indicated.

Dr. Philip D. Wilson, speaking June 23, 1942, at the Conference of Health Officers and Public Health Nurses at Saratoga Springs, said: "While heat, fluids, and sedatives are important in the treatment of shock, the really life-saving measure, when required, is transfusion of plasma or whole blood." He also stated, "The 'crush syndrome' is caused by the pinning of a person's extremity under falling timbers or débris from which it cannot be extricated for several hours. The individual seems in good condition until after

he has been released, when evidence of shock generally develops."

Treatment of Patient in Shock from Severe Trauma Without Hemorrhage or with Minimal Hemorrhage

1. Make the patient comfortable by first aid treatment to injuries (splinting of fractures, etc.). This would also include placing on stretchers and moving to casualty station or hospital by trained personnel.

2. Shock position—elevate foot of bed.

3. Record blood pressure and pulse at frequent intervals, as indicated by the individual case.

4. Maintain body temperature with warm blankets and hot water bottles. Do not overheat patient.

4. Sedation: Morphine sulphate by hypodermic as indicated to control pain. Do not increase shock by prescribing larger doses than necessary. Morphine syrettes, collapsible tube hypodermic outfits of morphine tartrate in one-quarter and one-half grain strengths are in the first aid kits of the Rochester Civilian Defense Units.

6. Administer oxygen in high concentrations by mask, nasal catheter, or tent, if these measures are available.

7. Fluid therapy: (a) Take blood for hemoglobin determination and blood grouping. (b) Cannulate accessible vein.

8. Fluids: First choice—half-strength plasma; second choice—matched whole blood if available, or compatible universal donor; third choice—6 per cent acacia in normal saline; fourth choice—5 per cent glucose in normal saline or Ringer's solution.

Many of the fluid substitutes for blood plasma and whole blood were studied by the committee. A beautifully written, detailed discussion of these is reported in the August issue of the *NEW YORK STATE JOURNAL OF MEDICINE*, Vol. 42, No. 15, page 1480. Time does not permit their repetition, however, this afternoon.

Treatment of Shock in Patient Suffering from Hemorrhage

1. Place patient in shock position with feet elevated. Quiet surroundings are desirable if possible.
2. Control external hemorrhage.
3. Appraise presence of internal hemorrhage. Appoint an individual surgeon to be responsible for this during the entire emergency and to have complete responsibility for laparotomy if necessary.
4. Record blood pressure and pulse at frequent intervals as indicated by the individual case.
5. Maintain body temperature with warm blankets and hot water bottles. Do not overheat patient.
6. Sedation: Morphine sulfate by hypodermic as indicated to control pain. In cases of suspected internal hemorrhage, postpone sedatives until the diagnosis of internal hemorrhage is established. Avoid increasing shock by prescribing larger doses than necessary. This deserves comment. Anoxia or deprivation of oxygen to body tissues is one factor present in shock because of depleted circulation. Morphine reduces the ability of body tissues to avail themselves of oxygen; therefore, overdosage of morphine in shock must be avoided. Pain only should be the signal for its use.
7. Drugs: If there is no response to shock treatment as outlined, adrenal cortex extract may be given—5 cc. intravenously or subcutaneously at the start, followed by 2 cc. at intervals of from four to six hours. No doubt many of us using adrenal cortex extract have not used enough.
8. Administer oxygen in high concentrations by mask, nasal catheter, or tent, if these measures are available.
9. Fluid therapy: (a) Take blood for hemoglobin determination and blood grouping. (b) Cannulate accessible vein. Concentrated blood, as shown by high hemoglobin where the victim may have been sweating and for many hours and deprived of water intake, may indicate the need for saline rather than blood or plasma.
10. Fluids: On suspicion of shock fluids may be administered in amounts indicated by the individual case. Attempt to control hemoglobin concentration and stabilize blood pressure. First choice—matched whole blood if available; second choice—half-strength plasma (1,000 to 1,500 cc. or more may be required); third choice—6 per cent acacia in normal saline; fourth choice—5 per cent glucose in normal saline or Ringer's solution.

Dehydration at the time of injury reminds us of dehydration at the time of operation. To divert for a moment to routine surgery in

civilian life—many patients enter the hospital the afternoon before operation. This becomes a more frequent occurrence with hospital crowding. Many times there has been hurry to finish certain details of home or business matters before the patient goes to the hospital to have the repair or hernia fixed. The patient has forgotten to drink and is not a good water drinker by habit. Very little or no evening meal is eaten. He is given a barbiturate or other sleeping drug. There is no breakfast. The schedule has been overcrowded, and the operation finally starts at ten-thirty, eleven, or twelve o'clock. Many nurses have been taught that no fluids should be given before operation to avoid vomiting. How long before is variable in their training. Because of these factors, such a patient may go into shock with a simple hernia or perineal repair. The necessity of plasma can often be avoided by intravenous saline started at the beginning of the operation. The patient could and should have had water and fruit juices forced the night before and water up to two hours before operation time. A clean, well-watered stomach is less liable to vomit. A practical means of judging fluid reserve in injured or preoperative patients is the color and amount of urine. A dark urine usually indicates dehydration. A large amount of light-colored urine over a period of a few hours would indicate good fluid reserve.

Treatment of Shock in the Burned Patient

1. Place patient in a comfortable position (on a sterile sheet if available).
2. Check extent and severity of burned area and make a written record.
3. Record blood pressure and pulse at frequent intervals as indicated by the individual case.
4. Maintain body temperature with blankets over a sterile sheet if available. Do not overheat patient.
5. Sedation: Morphine sulfate in amounts as indicated by the individual case. Again, pain is the only indication for morphine. Bear in mind the danger of overdosage in very old, very young, or badly shocked casualties.
6. Shock position—feet elevated.
7. Drugs: If adrenal cortex extract is available, it may be given at the discretion of the surgeon in charge. Dosage: 5 cc. may be given intravenously or subcutaneously at the start, followed by 2 cc. at intervals of from four to six hours. Adrenal cortex is much more readily carried in the first aid kit than plasma and might often be indicated at the site of the casualty, with the blood or plasma given after the victim has been moved to the hospital.

8. Administer oxygen in high concentrations by mask, nasal catheter, or tent, if these measures are available.

9. Fluid therapy: (a) Take blood for hemoglobin determination and blood grouping and for specific gravity and hematocrit if facilities are available. (b) Cannulate accessible vein. (c) Start full-strength plasma intravenously at the rate of 200 cc. plus per hour or more rapidly if the blood pressure is falling. Continue for at least eighteen hours if hemoglobin percentage is tending to increase. During the second twenty-four hours combat hemoglobin concentration with half-strength plasma in amounts

as indicated by the individual case. In large area burns, the weeping or skin loss of plasma is often sufficient to cause a relative concentration of hemoglobin. (d) If burn exceeds 15 per cent of the body surface, begin full-strength plasma injection, whether or not patient shows signs of shock during the early treatment.

10. Do not begin local burn treatment until blood pressure is stabilized.

11. During the second twenty-four hours maintain near normal hemoglobin or hematocrit level by: (a) fluids by mouth; (b) equal parts of plasma with normal saline intravenously as indicated.

TREATMENT OF WAR FRACTURES AMONG THE CIVILIAN POPULATION

J. P. HENRY, M.D., Rochester, New York

SOMETIME ago Dr. Simpson requested Drs. Clark, Crawford, Harris, Hopkins, and me, representing the Fracture Services of the hospitals included in the Emergency Medical Service of the local Civilian Defense Organization, to act as a committee to draw up an outline for treatment of fractures. The outline will be a recommended catalog of more or less standardized procedure for use in any major disaster. After several meetings with discussion of the literature, the proceedings of recent orthopaedic meetings, and personal experiences, we evolved a brief summary of recommendations, which, I believe, has been or will be made available to all of you. This represents, we believe, the consensus of present opinion on the subject, and this presentation today will be an expansion of the outline. Some of it may seem elementary and self-evident, but experience has shown that it is well worth while for all of us to refresh our memories on some perhaps well-known facts and to coordinate and arrange our ideas so as to afford us a fairly definite and well-thought-out routine which will serve us as a very valuable foundation in carrying on this phase of medical service under the extreme stress of a major disaster. Also it must be remembered that, because of the enforced shortage of available personnel, many details of this work will fall on relatively inexperienced lay rescue squads—first aid workers and the like—or on doctors whose normal professional activities are far removed from the care and treatment of fractures.

Hence, I must ask that you bear with me if I present ideas that may seem well known and rather primary to you. I assure you again that experience has shown them to be well worth emphasizing.

"War fractures" among the civilian population are, of course, basically the same as "peace fractures" among the same group, but "war fractures" are complicated by a number of factors. They are apt to be more severe, with a much higher incidence of compounding wounds. There may be multiple fractures or fractures associated with other injuries in the same individual. Patients are apt to suffer from shock beyond the ordinary degree because of the severity of their injuries, exposure, unavoidable delays in rescue work, and psychic influences. Treatment may be modified by extraneous circumstances, such as blackouts, shortage of experienced personnel, sudden and large influx of casualties, and even by bombs affecting the hospital itself with either direct or indirect disruption of essential services, such as light, water, or communications.

We have roughly divided the treatment of these injuries into two stages:

1. Treatment in the field.
2. Treatment in the hospital.

Treatment in the Field

Field treatment of fracture cases will, of necessity, largely fall into the hands of lay personnel working under more or less medical supervision.

The first and most important dictum is that all fractures should be immobilized before the

victim is moved unless it is absolutely necessary to move him forthwith from a place of imminent danger. Obviously one does not stop to apply any elaborate splinting to a man who is in a blazing room or who is lying alongside a wall which is beginning to collapse, but in general fracture victims should be "splinted where they lie." Splints, stretchers, etc., should be brought to the victim, not the victim to the splint. If there is a suspicion of fracture, treat as one would a fracture. No harm will be done by splinting an unbroken bone in error, but much harm may result from neglecting to splint a questionable injury which later proves to have been a fracture. To be of any value a splint must effectively accomplish its purpose, viz., the immobilization of the fractured bone. To do this it is necessary, generally speaking, to immobilize the joint above and below the fracture. Traction-fixation splints which overcome the effects of muscle spasm are, at least theoretically, the most desirable form of splinting. From considerations of a practical nature, there has been a great deal of argument pro and con regarding the use of traction splints, but we have recommended the use of the Keller-Blake or modified Thomas hinged, half-ring splint for use in fractures of the upper leg or thigh. This splint can be fitted to practically any thigh and is interchangeable from right to left. For fractures of the lower leg or ankle, the well-known pillow splint makes a very satisfactory appliance. For fractures of the upper extremity, we have recommended the use of lateral splints, with immobilization of the extremity in a sling or by a secure fastening to the trunk. Fractures of the jaws may require provision for an adequate airway, after which they can be held with a four-tailed bandage or the simple Red Cross jaw bandage.

There has been a great deal of difference of opinion regarding the use of traction splints, especially in the case of compound fractures in which one of the fragments protrudes through the wound, and we have had some correspondence with the National Headquarters of the American Red Cross and with Dr. Robert Kennedy, Chairman of the Fracture Committee of the American College of Surgeons, who supervised the preparation of the portion of the Red Cross *First Aid Manual* dealing with this subject. The authoritative consensus of opinion seems to be that, from a practical standpoint, it has been considered necessary to prescribe a definite form of procedure, designed to fit most cases and not complicated by exceptions that would tend to confuse inexperienced personnel. Fractures of the lower extremity—e.g., those for which we have recommended traction splinting—come within one of the following groups:

1. Simple fractures, with no compounding wound.

2. Compound fractures in which the wound is caused by a projectile or other external object—i.e., from without inwards. In these cases, any infection has already been carried into the wound.

3. Compound fractures with the wound produced from within outwards, in which the protruding fragment has already replaced itself within the wound before the case is seen by the first-aiders. Again, any infectious material has already been carried into the wound.

4. Compound fracture, with the fragment still protruding through a relatively small wound. This type constitutes a small percentage of the cases.

In the first three classes, there can be no objection to the use of traction. The last class is the basis for the controversy, and Dr. Kennedy writes that the American College of Surgeons' Fracture Committee feels that the beneficial results of traction splinting in the first three classes outweigh the possible detrimental results of its use in the fourth. Personally, I have found that the accidental replacement of the protruding fragment within the wound, when splinting, may often be prevented by the simple expedient of placing a sterile compress under the protruding bone end.

If conventional splints are not available, very satisfactory substitutes can be improvised from materials at hand if one keeps clearly and definitely in mind just what he is attempting to accomplish by the application of the splint.

Compound fractures present additional problems. First, of course, is hemorrhage. In the great majority of cases, this can be controlled by the pressure of a dressing, and a tourniquet is unnecessary. A poorly applied tourniquet can increase hemorrhage by shutting off venous return flow and leaving the deeper arterial flow into the extremity unaffected. If a tourniquet is used, the victim should be conspicuously marked. The officially adopted method is to mark "TK" with red skin pencil or lipstick on the patient's forehead, with the time of application. No tourniquet should be left on longer than absolutely necessary and should be loosened at intervals not to exceed twenty to thirty minutes. In addition, any doctor through whose hands a TK patient passes should carefully observe the condition of the extremity distal to the tourniquet as well as check the time of application.

The second complication of compound fractures is the possibility of infection. We feel that no attempt should be made to apply antiseptics in the field, except that, if sulfanilamide

powder is available, it may be dusted into the wound, which should then be covered with a sterile dressing, and the fracture should be splinted.

Of course, appropriate measures for the prevention or relief of shock, as outlined by Dr. Barnard, should be instituted, although it should be remembered that effective splinting of a fracture is an excellent measure in preventing or relieving shock by removing a major cause.

Transportation of the Fracture Case.—All major fracture cases should be transported as stretcher cases and marked "Urgent." Particular care should be given to the transportation of patients with probable or even possible fractures of the spine. This condition is the one which is most often badly handled or actually maltreated in the ordinary accidents of civilian life, when patients with injured backs are so often folded up in a sitting position in the back seat of an automobile and rushed to the hospital. As stated previously, if in doubt as to the presence of a fracture, treat as a fracture. This is especially true in injuries of the spine. Any victim who complains of pain in neck or back should be considered a case of fracture of the spine until the contrary is proved. Note should be made of ability to move arms or legs, for knowledge of the time of onset of any paralysis is of great help in the later treatment of the case. A victim with an injured neck should be transported lying on the back with the head firmly immobilized by pillows, sandbags, or manually in order to prevent motion of the neck in any direction. Because of the usual mechanism of the production of fractures of the dorsal or lumbar spine—viz., hyperflexion—this type of case should be transported in a position of hyperextension, which is most readily maintained by carefully rolling the victim over onto his face and transporting him in this position. In this type of case one must keep firmly in mind that "haste often makes waste" and that a little delay while arranging proper means of transportation may be less harmful than hasty moving of the victim with possible aggravation of the already existing trauma and resultant cord injury with permanent disability or even mortality.

Treatment in the Hospital

The first contact with the fracture victim on his arrival at the hospital will be through the admitting or receiving officer. May we digress to emphasize that this assignment should be delegated to one of the most competent men on the staff. He must, after the briefest of examinations, be able to make an accurate diagnosis of the patient's injuries and an evaluation of his

general condition; furthermore, he must decide with a minimum of hesitation or delay what treatment is indicated, what treatment the case can tolerate, and, in case of multiple injuries, the priority of the various conditions requiring treatment. He should check at once for the presence and degree of shock, for hemorrhage, for the presence of a tourniquet, with the time of its application and the condition of the extremity distal to the tourniquet, for compounding wounds, for efficiency of splinting, and for the presence of other injuries such as abdominal or intracranial. He must do all these things speedily and without delay, yet he must also do them accurately and all-inclusively. This is definitely a most important and exacting assignment.

Treatment for shock, when indicated, must be instituted at once. One does not have to worry much about results of treatment for fracture in a patient who has already died of shock. It must be remembered that several things can be going on at the same time and that, along with specific shock treatment, more effective immobilization of a fracture may assist in some cases in the resuscitation of the victim.

Generally speaking, all fractures should be reduced and permanently immobilized as quickly as possible but, depending upon the exigencies of the situation, priority is to be given to compound fractures, the treatment of closed fractures, if they are adequately splinted, being delayed until the situation permits it.

Immediately on admission, all compound fracture cases should be given antitetanus serum or tetanus toxoid, and administration of sulfadiazine, by mouth, should be instituted. Routine administration of antigas serum has not been recommended because of (1) lack of substantial agreement on the efficiency of the commercially available serums, (2) their scarcity and expense, and (3) the results of the use of the sulfonamides.

Unless hemorrhage or the time element interferes, *x-ray examination* should be made before reduction is attempted, as much waste of time may thus be obviated.

Preoperative preparation of the operative field should begin with a thorough cleansing with soap and water of the adjacent areas, shaving as indicated, followed by the use of tincture of iodine (2 to 4 per cent) on the surrounding skin, not in the wound.

Anesthetics.—Spinal anesthesia should not be used in shocked patients. Gas-oxygen anesthetic should be administered by an experienced anesthetist. If it is not available, ether should be used. In selected cases, local or regional anesthesia may be employed.

Type of Operation

The type of operation will have to depend upon the type of case and the judgment of the surgeon. It cannot be dictated that one method shall be followed in all instances. The patient cannot be made to fit a favorite method. We will attempt to present what seem to be generally accepted as the most desirable and effective procedures, even though we realize that these may be modified by many factors; e.g., the condition of the patient, the time elapsed, the experience of the operator, and the facilities of the hospital.

All authorities are generally in agreement that the first essential is thorough and effective débridement of all traumatized tissues. This requires that the wound be enlarged, if necessary, to permit access to all parts of the wound in order to allow thorough mechanical removal of damaged and contaminated tissue. If irrigation is used, the flow should be directed from within outward.

This cleansing of the wound should be followed by as accurate a reduction of the fracture as possible. Reduction should be maintained by rigid internal fixation with plates, screws, or wires if feasible. Traction by multiple pins (one or more pins distal and one or more proximal to the fracture), by single pin, or by Kirschner wire may be used.

One of the sulfonamide drugs should then be introduced into the wound in powder or crystalline form. Sulfanilamide is recommended by most authorities because it has seemed the most successful, possibly because, experimentally, it shows the highest concentration in the serum locally and the deepest penetration into tissue. The wound should then be left open and packed with plain or vaseline gauze and covered with a gauze dressing. This should be followed by the application of a well-fitting plaster-of-paris cast. This completely immobilizes all the tissues of the extremity and, by producing an approach to a condition of physiologic rest, enhances the ability of the tissues to resist infection and promote healing. No window should be cut in the cast, as this immediately destroys its effectiveness by permitting edema, stasis, and contamination with cross infection. Unless complications arise, the cast should not be changed for several weeks or longer if possible, unless it is softened by excess drainage or a change is made unavoidable by a foul odor. If there is uncertainty regarding the circulation in the part or the effectiveness of débridement, application of the cast may be postponed for several days and some form of open traction employed, perhaps supplemented by a plaster gutter splint to permit observation of the part.

This procedure was well summarized by Dr Philip D. Wilson in a paper reported in *Health News* of July 27, 1942:

"Operative treatment of the wounds aims at mechanical sterilization by excision of all dead and contaminated tissue. This is followed by the introduction of one of the sulfonamide drugs in powder or crystalline form in the wound, which is then packed open with vaseline gauze. Primary closure of wounds is dangerous and bad practice. When a fracture is present, it is reduced, and the injured limb is then enclosed in plaster. The closed plaster treatment of compound fractures according to the Orr-Trueta technic has proved highly successful. It saves the time and labor of doctors and nurses in daily changing of dressings, conserves the materials, and saves the patient pain from daily manipulation of his wound. It promotes healing of the wound by providing complete rest of the part and prevents cross contamination and mixed infection of wounds which always occur in spite of the best surgical technic when dressings are changed frequently."

Necessarily, in the short time at our disposal, we have only attempted to sketch briefly the highlights of this most important subject, and we hope that we may at least have aroused your interest sufficiently to inspire you to do some serious thinking and planning as a foundation for the most efficient care of this type of injury, if a major disaster should come upon us.

Outline of Standardized Treatment of Fractures by E. M. S.—Civilian Defense

In the Field

1. All fractures to be splinted adequately *before* transportation. "Splint them where they lie."
2. Compound fractures to have sulfanilamide (if available) dusted into wound and wound dressed with dry sterile dressing. Fracture splinted.
3. Tourniquet to be applied only if absolutely necessary. Medical officer at any station through which tourniquet case passes should check not only time of application but also condition of extremity distal to tourniquet.
4. All cases with compound fractures and/or tourniquet should be conspicuously marked, preferably with some conspicuously colored tag, or by dye on forehead.

In the Hospital

1. Admitting officer should check tourniquets, presence of compounding wound, and adequacy of splinting.
2. In compound fractures, oral administration of sulfadiazine should be begun at once and A.T.S. or tetanus toxoid administered.
3. Shock treatment should be initiated when indicated.
4. As a general rule, all fractures should be reduced and permanently immobilized as quickly as possible but, depending on the exigencies of the

situation, priority is to be given to compound fractures, the treatment of closed, but adequately splinted, fractures being delayed until the situation permits.

4. Ample supply of sulfadiazine for oral administration and sulfanilamide for use in the wound should be available.

Also adequate supplies of pins, S.M.O. plates and screws, Kirchner wires and bows, silver wire. Thomas leg splints and plaster of paris should be available.

5. Standard preoperative preparation:

Thorough cleansing of *area about wound* with soap and water. Shaving as indicated.

Tincture of iodine (2-4 per cent) on skin—not in wound.

6. Operative procedure:

This will depend on the type of case and the judgment of the surgeon.

As a general rule, the use of sulfanilamide in the wound after débridement and the leaving open of grossly compounded, contaminated wounds are recommended.

Round Table Discussion

After the four papers were presented, Dr. Leo F. Simpson asked questions of the authors and others.—Editor

Question: Have pitressin and epinephrine any value in shock?

DR. EARLE MAHONEY: No. Vasoconstriction may elevate blood pressure, but it does not prevent protein or fluid loss from circulation. Any possible benefit would be very temporary, and ultimate harm would result. Vasoconstriction would be added to coronary circulation in a heart already suffering from anoxemia. Depleted circulation to the heart would result. Adrenal cortex hormone (eschatin) in 5 cc. and repeated in 2 cc. doses would be better.

Question: What is the present status of the value of adrenal cortical extract in the treatment of shock?

DR. MAHONEY: The theoretic value of adrenal cortical extract is that it reduces the capillary permeability. Over a period of time in shock resulting from burns this reduction of capillary permeability would minimize the amount of fluid lost. We have seen burns with and without adrenal cortical extract treatment and have seen no difference.

DR. BARNARD: Right or wrong: Patients in shock should not be removed hastily to the hospital lest the excitement and jolting of transport result in increasing shock of serious proportions. This is now the English plan.

The English experience was to move the patients to the hospital as rapidly as possible. Through necessity they found that it was better not to move them too quickly. It is better to treat them at the site of injury. One must, however, bear in mind the type of crushing syndrome. If a victim has been pinned down by heavy timber, etc., for several hours, he should be quickly treated even if the hospital is not nearby because he is likely to go into shock very rapidly.

Question: How many fatal reactions have there been to plasma?

DR. HOWLAND: In the United States there has been one fatality to plasma. This was caused by dried plasma which was not prepared according to

the standard and accepted procedure. When it was rechecked, it was found to be definitely incompatible plasma.

Question: Do you think A and B factors will be added to blood plasma to get rid of any anti-A and -B antigens that might be present in the plasma?

DR. HOWLAND: Reactions to anti-A and -B substances have been less than 3 per cent, including the total number of reactions. This also includes plasma given by untrained individuals, and we consider it a relatively standard figure for the whole medical profession. The less we do to plasma in preparation, the less chance there is of contaminating it. That is about the present opinion of this committee and also of the Civilian Defense Committee. Until we have more reason for adding extra substances, we shall not add anti-A and -B substances.

Question: If staphylococcus and saprophytes are the most common contaminants, why use merthiolate, which does not prevent this contamination?

DR. HOWLAND: When we started, we did not use any preservative at all. The feeling of the committee was that if we did not use a preservative, we were open to criticism. Merthiolate is one of the few products that can be injected intravenously without reaction and that does not denature protein.

Question: How many cases of mercury poisoning will occur, especially in people who are sensitive to mercury or who receive a very large amount of plasma?

DR. HOWLAND: There are two cases on record in which individuals with burns developed mercury poisoning after receiving large amounts of plasma. Hence it is being stressed that if an individual is burned, plasma should not be prepared in this fashion. Special plasma can be made up without a preservative. If anything in excess of 1,500 cc. is given, we suggest that the preservative be omitted.

As for individuals who are sensitive to mercury—one has to take that chance.

Question: Is there any difference in the properties of wet plasma, frozen plasma, and dried plasma?

DR. FRED A. BRYAN: There is very little difference in them. In shock, plasma is used mainly for the effect of osmotic pressure. It is used primarily for the albumin in the plasma so that dried, frozen, or wet would be satisfactory. However, there is slow deterioration of wet plasma whether it is kept on ice or at room temperature. It can be kept at room temperature for a considerable period. You will find that the fibrin precipitates in wet plasma, and substances such as prothrombin and complement are lost after twenty-four to forty-eight hours.

Frozen and dried plasma are roughly the same. The only difference is in their transportation. The frozen must be kept at a temperature of -20°C . and must be melted in a constant-temperature bath at the source of storage and then transported. For large quantities, it is quite a job to maintain a constant-temperature bath at 37°C .

Dried plasma is the best type for transportation. Frozen plasma is in the city, and we must keep a supply in Rochester available on call.

Question: How do burned areas become infected if it is true that they are sterile or nearly so at inception?

DR. JOHN DETRO: It is essentially true that burned areas are sterile at the time of their inception, but through contact with unclean objects, which might be clothing, unsterile instruments, and dressings, they may become infected. It is very important that sterile procedure be used from the start of treatment.

Question: What type of graft is advisable after removal of the eschar?

DR. DETRO: Pinch grafting is generally considered to be a surgical error except in very large areas. Then pinch grafts can be used without moving the patient from bed. The best graft, however, is the split-thickness graft.

Question: In treating burns, what are the chief complications to be watched for and avoided if possible?

DR. HOUCK: Shock and infection are the chief complications. In shock, use plasma.

For infection, begin by preparing the patient properly. Use Ivory soap and water, gentleness and care in débriding all ivory-white dead tissue. If there is subsequent infection underneath the crust, open the crust where you find loose, puffy area and apply fresh Dakin's solution. When the infection clears, use tannic acid and silver nitrate.

Question: What is the best method of splinting injuries near the joint, in which a differential diagnosis between fracture and dislocation cannot be made in the field?

DR. HENRY CRAWFORD: If it is an ankle joint, I should say a pillow splint, in any event. If it is a knee or an elbow, the affected joint could be straightened by very gentle traction. Routine fixed traction splinting would be very satisfactory and would do no harm if properly applied. If the knee or elbow joint cannot be straightened out with gentle traction, well-padded coaptation splints on the outside of a pillow snugly wrapped around a joint would probably be the best method of immobilization. If it is the hip joint, fastening the two legs together with a pillow between the knees would probably be the best method of splinting. In case of an injury about the shoulder joint in which the elbow cannot be placed to the side of the body, the patient should be transported on a stretcher with the arm supported by pillows between the elbow and the body, in the most comfortable position. Some patients with dislocated shoulders, who show no evidence of any shock, would rather support the injured arm with the other hand than allow any type of binding splint to be applied.

Question: What is the recommended dosage of the sulfonamide drugs orally and in the wound?

DR. HENRY: Orally—sulfadiazine, 1 grain per pound of body weight up to 90; wound—2 to 10 Gm. sulfanilamide powder.

Question: How long after injury is débridement still indicated?

DR. HENRY: Up to six hours—optimum; good prognosis; six to twelve hours—débridement still should be done but prognosis deteriorates with time; after twelve hours—débridement should not be done; wound simply enlarged for drainage.

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS OFFERS PRIZE

The National Society for the Prevention of Blindness announces that a prize of \$250 will be awarded for the most valuable original paper during 1943 adding to the existing knowledge about the diagnosis of early glaucoma. The award will be made by the Society, with the guidance of an ophthalmological committee composed of Dr. Arnold Knapp, Dr. Manuel Uribe Troncoso, and Dr. Mark J. Schoenberg.

Papers may be presented by any ophthalmologist, student in ophthalmology, or research worker of the western hemisphere and may be written in English, French, German, Italian, Spanish, or Portuguese, but those written in the last four languages should be accompanied by a translation in English. Papers should be in the office of the National Society for the Prevention of Blindness, 1790 Broadway, New York City, by September 15, 1943.

"A budget," said Dr. W. E. Ryan, of Midland (Texas), "is a method of worrying before you spend

the money, instead of afterward."—*Texas State Journal of Medicine*

FACTORS IN OBSTETRIC CARE

Report of a Rural Study

HENRY R. O'BRIEN, M.D., Hartford, Connecticut

A PROGRAM in 1937 for mothers, infants, and preschool children was set up in Cattaraugus County, with the aid of the Children's Bureau, the State Department of Health, and the Milbank Memorial Fund. This program, which followed a survey by Dr. Doris Murray of the Children's Bureau, was approved by the County Medical Society and adopted by the County Board of Health. It was supported by an increased appropriation by the County Board of Supervisors.

A part of the program was a study of the factors in maternal care which might have a bearing on maternal and infant mortality. A questionnaire was prepared for physicians and I should like to acknowledge substantial assistance from Dr. Joseph P. Garen in this. Through the cooperation of the State Department of Health, the questionnaire, printed in blue, was interleaved with standard birth certificates in booklets prepared especially for use in Cattaraugus County (see Chart 1). The doctor was asked to fill out the slip when he made out the birth certificate, sending the latter to the local registrar and the former to the Department of Health.

These booklets were distributed through the local registrars to all physicians handling deliveries in the county. The blue slip bears an explanation itself, and this was supplemented by other publicity through the medical society, staff meetings, and ordinary contacts with physicians. No attempt was made to call on each physician separately.

The slips were prepared and circulated by July 1, 1937, in time to include the latter half of that year. They were continued during 1938 and 1939. At the close of a quarter a check was sent to each physician, reimbursing him fifty cents for each slip received from him. This helped to keep up his interest. We paid physicians in the county for reports on deliveries in the county, whether the mother resided in the

county or not, but out-of-county doctors were paid for reports only on county mothers.

Meanwhile, a summary sheet and a code had been prepared, with the aid of Miss Dorothy Wiehl of the Milbank staff and of Dr. Jacob Yerushalmy of the State Department of Health, now of the Children's Bureau. The blue slips were coded on the summary sheets in our office in Olean and later transferred to punch cards in New York.

As the study developed, it occurred to us that it might well be extended to cover the prenatal, delivery, and postpartum services of the public health nurses. An experienced clerk was sent to the district offices to take this information from the nursing records. The Olean Red Cross Society and the Gowanda Red Cross permitted the extension of the survey to their records. Since the nursing study included care for a year after delivery, it closed in the summer of 1940 for the babies delivered up to July 1, 1939.

The summary sheets also included material from the birth certificates and from infant and maternal death certificates. A special 81-column Hollerith punch card was printed for the study (see Chart 2). These have been sorted, largely in New York, but a few in Hartford. The figures obtained are discussed in the following paragraphs.

In the two years and a half of the Blue Slip Study, 3,562 births were reported as occurring during that period. Of this number, blue slips were received from physicians on 2,243 resident babies and 643 nonresident, or 81 per cent of the births. The percentage was slightly higher among nonresidents, probably because the more interested physicians had the wider practice.

Of the 2,896 resident births, a physician signed the birth certificate in all but 9 (99.7 per cent). The midwife plays a very minor part in Cat-

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1942.

Formerly Commissioner of Health, Cattaraugus County, New York; now Chief, Division of Local Health Administration, Connecticut State Department of Health.

This study was made possible by grants from the Milbank Memorial Fund and by the cordial cooperation of the Cattaraugus County Medical Society. Dr. H. C. Allen served as chairman of the Maternal Welfare Committee during most of this time. Among others, appreciation is expressed of the thoughtful industry of Miss Frances McNamara and Miss Kathleen Cramer.

Prenatal Care

Blue slips were received for 2,243 resident births, but not for 653 others that occurred in this period. Studying these, we get considerable information as to quantity of service, but of quality, that elusive item, we can judge only by inference.

Most of the women who saw the doctor one to three times probably did so toward the end of normal pregnancy, past the period of prematurity with its dangers to the infant. The largest number of times reported was seventeen for one patient, but 33 were seen twelve times. Olean had a slightly higher proportion in the last two groups.

Yet 205 patients, not yet delivered, did not see the physician at all in the ninth month, although most had had some prenatal care. Of those seen in the ninth month, 838 were seen but once, 671 twice, 130 three times, 164 four times. Two were seen nine times in the last month.

How early in pregnancy did these patients come?

A total of 40.5 per cent started care in the first trimester, 32.2 per cent in the second, and 22.3 per cent in the third. In Wisconsin² care was earlier, but a larger proportion had no prenatal care. A larger proportion of Olean patients saw the physician in the first or second month of pregnancy than was the case elsewhere in the county.

Some study was made of the 78 patients (live and stillbirths) who had no prenatal care at all. They were fairly evenly divided between urban and rural. Thirteen (8 urban, 5 rural) were primiparae. Economically, they rated 8 "good," 26 "fair," 23 "marginal," and 17 "welfare."

TABLE 2.—MONTH OF PREGNANCY IN WHICH PATIENT FIRST VISITED PHYSICIAN (LIVE BIRTHS)

Month	Number Visiting	Percentage	Infant Deaths Number	Mortality
1	114	5.4	10	87.7
2	296	13.9	9	30.4
3	453	21.3	11	24.3
4	318	15.0	14	44.0
5	235	11.1	16	68.1
6	240	11.3	9	37.5
7	211	9.9	8	37.9
8	148	7.0	11	74.3
9	111	5.2	5	45.0
	2,126	100.0	93	43.7

In the list of the usual complications of pregnancy the most prominent were toxemia (36), a milder kidney involvement (64), eclampsia (6), and high blood pressure (29). Where reports were made, 1,487 (84.8 per cent) had no complications.

Place of Delivery

Private homes were the place of birth in 1,151 instances (39.7 per cent), the five hospitals in 1,670 (57.7 per cent), and three small maternity homes in 75 (2.6 per cent). Institutions thus delivered a total of 1,745, or 60.3 per cent. The proportion rose each year—53.8 per cent in 1937, 60.1 per cent in 1938, and 63.8 per cent in 1939. For total births in the county the figures for these years would be higher, since non-residents come almost entirely to be delivered in institutions. We are interested here also in getting the resident custom. In Mississippi,⁴ in 1938, 26 per cent of the deliveries were in hospitals, but in Michigan 45 per cent.²

How far do mothers go to be delivered? To get a clearer answer let us separate the rural remainder of the county from the three urban areas of Olean, Salamanca, and Gowanda.

Only 10.9 per cent of the rural births were more than ten miles from the mother's home.

Operations

Operative intervention was reported on 1,003 of 2,719 resident and nonresident patients (live and stillbirths included), or 36.9 per cent. An additional 17 had lacerations not due to operations, while 1,699 (62.5 per cent) had no operative experience. It is noted that operative habits depended somewhat on the scene of the delivery. Forceps were less often applied in the home, although they numbered 23 mid and 6 high, mainly in the rural areas. Three versions were performed in the home. The bulk of the operations were performed in the hospitals. There was little surgery in maternity homes, save one conducted by a registered nurse. The percentage of patients subjected to cesarean section varied from 0.6 (Hospital B) through 2.5 (C) and 4.2 (A)

FREQUENCY OF PRENATAL MEDICAL SERVICES

CHART 3.

to 6.2 (D) and 7.8 (E). In the two latter, section was sometimes performed to sterilize welfare multiparas. In Hospital D forceps were applied to 62.3 per cent of the babies, for 55.8 per cent of whom episiotomy was also done. Version, however, was more common in each of the other hospitals.

The use of forceps in 30.0 per cent of all deliveries may be compared with 14.5 per cent in the Michigan study² and 14.1 per cent in Wisconsin.⁴ High infant mortality was associated with high forceps, version and cesarean section. The infant mortality among babies born without operation in Hospital D was 89.9 and in Hospital A it was 75.7. Prematures bulk large in this group.

During the study, 14 maternal deaths occurred in 2,896 resident births, a mortality of 4.8. Five followed the 80 cesarean operations, an operative mortality of 6.25. Three were in Hospitals D

and E. Four deaths were from hemorrhage (one a ruptured ectopic), three from toxemia, and one each from shock and sepsis. Only two of the group were connected with abortion

Influence of Economic Status

The doctor was asked to indicate the approximate economic status of the patient, using four groups: good, fair, marginal, or welfare. In the office we also listed those applying or accepted for medical care by a welfare department. Usually the doctor and the welfare worker considered the family in the same group. Some "marginal" cases applied for welfare aid, and some were accepted, others not. At least two "fair" families made welfare application,

and one apparently established its case and was accepted.

The proportion of mothers delivered in hospitals fell markedly with the means of the family. It rose slightly in the welfare group because at times doctor, nurse, and welfare worker agreed that home conditions were too poor to permit a safe delivery. Among rural residents the rates were lower, being higher in the urban districts.

It was the rural borderline mother who received pitifully little hospital service. Instead she turned more often to the public health nurse, to a relative, or to a friend; or, more often than any other group, she had no one at all to help the doctor.

In each separate economic group the largest number of prenatal patients saw the doctor for the first time in the third month. Studying trimester groups, however, we note that the proportion of those starting prenatal care in the first three months of pregnancy is much higher in the "good" economic group and falls off rapidly in the others. In the second trimester the figures are almost uniform, but in the third

TABLE 6—INFLUENCE OF RESIDENCE AND ECONOMIC STATUS ON EARLY PRENATAL CARE

Total					
All residents	708	819	391	269	2,187
Rural	228	417	246	168	1,059
Urban	480	402	145	101	1,128

the proportion rises as the family's financial ability falls. Rural residents are somewhat slower in starting care than urban, especially in the "marginal" group. One in 90 of the upper group had no prenatal care at all, one in 16 had none in the "welfare" group.

Both residence and economic status of the family have a striking influence on the frequency of operative intervention (see Chart 4). Rural residents are less than two-thirds as liable to be operated on as are their city sisters. The frequency of operation rises with financial ability, though "welfare" mothers had more operations than "marginal" mothers. A city woman of means had an operation three and one-half times as frequently as a rural woman just off welfare.

Even when only hospitalized cases are considered, these differences persist, though less strikingly. The four economic groups received intervention to the following degree: 59.7 per cent, 52.6 per cent, 41.6 per cent, and 46.8 per cent, or an average of 53.8 per cent. The rural curve is flatter, with 53.2 per cent, 45.5 per cent, 42.0 per cent, and 43.2 per cent, or an average of 47.1 per cent. The urban figures are higher and sharper: 62.0 per cent, 57.3 per cent, 41.2 per cent, and 58.8 per cent, averaging 57.6 per cent.

Length of Gestation

Of the 2,870 resident living births, 60 occurred before the eighth month of pregnancy, 62 more during the eighth, and 3 were described as "premature"; 125 (4.0 per cent) came before the ninth month and may be classified as premature. Fifteen were reported as "overdue." The rest were born sometime during the ninth month. Of the premature births, 52 (41.6 per cent) died. None survived before the sixth month, but 12 per cent of the 17 born in the sixth month lived, as did 54 per cent of the 41 born in the seventh month and 77 per cent of the 62 born in the eighth. Premature infants survived better than average in Olean and poorer in Salamanca.

We have definite weights for 2,122 babies born alive; 116 (5.5 per cent) weighed less than 5½ pounds. Of these, 37 (31.9 per cent) died. A Salamanca infant weighing 2 pounds 14 ounces at

CHART 4.

birth managed to survive although 10 others weighing less than 3 pounds died.

Rural weights were slightly higher than urban; and 36.9 per cent of the urban and 22.8 per cent of the rural died.

Postpartum Examinations

When he filled out the blue slip the physician stated his intention in 98.9 per cent of the cases of making a postpartum examination. The nursing records, studied for the following year, have some bearing on this. For 396 cases there was no postpartum examination in 160. Of this number the reason is not given in 89 cases; in 10 the doctor said it was not necessary; 37 mothers refused, while 24 returned to the doctor, but he made no pelvic examination. In 249 cases the patient saw the physician and some examination was made, but in only 10 instances was this stated definitely to have included a pelvic examination. In many cases, of course, the service was complete, but too often a gap existed. Whether the responsibility was with the patient or with the doctor, the patient did not have the check-up that we all believe is called for after maternity.

To what extent do families tend to switch doctors? The question is answered in part by a study of birth and death certificates of the 123 resident infants who died. In 21 instances, or 17 per cent, a different physician signed the death certificate. In 12 cases the baby was born

at home and was cared for there throughout. In 6 cases the baby was born at home and died in a hospital. Eleven babies were born in a hospital, went home, and returned as their condition grew worse. In 3 cases another physician was in charge.

The Questionnaire as a Method of Survey

In such a survey as this the physician is usually visited in person by an investigator, who may be a medical member of the staff, a nurse, or a clerical worker. Each plan has its advocates. But salaries are expensive. A questionnaire obviously costs less even when a fee is paid. What are the relative advantages otherwise?

An investigator might possibly gather material on a higher percentage of births. Our questionnaire, which secured answers concerning 78.1 per cent of the resident births, was more than normally successful for a questionnaire. This suggests a cooperative group of physicians. Yet an investigator who interviewed 95 physicians on 3,562 births in two years and a half would work steadily. We might expect an investigator to have practically all his returns complete, but this questionnaire has been excellent in this respect.

Would he be more accurate? Accuracy would seem largely to depend on the carefulness, intellectual honesty, and interest of the practicing physician and upon the interval before the report is made. To study the second factor, first note Table 8.

An investigator might have difficulty in seeing a large group of doctors earlier than three months in more than 88 per cent of the births. The personal factors probably balance. The doctor might be interested in the investigator's visits, repeated, they might irritate him.

This is admittedly a priori reasoning. One bit of objective evidence deals with Wassermann reports. The doctor's statement that the result of the Wassermann was negative was verified by the laboratory reports in 1,027 cases, not in 15 others; that it was positive in 40 cases, not in 3 others. That was an agreement of 98.3 per cent. However, in 400 other cases the Wassermann was reported as taken but there was no record of the results.

New York State and New York City and Wisconsin are now collecting part of this information on the birth certificate itself.

One usual accompaniment of such a study was lacking. The infant mortality did not show any marked drop, as so frequently happens. Perhaps the absence was due to the fact that the county has seen other health studies and so was less susceptible to one alone. Infant mortality continues to show a steady decrease, however, over a period of years.

Public Health Nursing

This study brought out much material on public health nursing in maternal and infant care. For this section items are selected which are of special interest to us as physicians or health officers.

The modern physician wants his obstetric patients in the hospital, or at least he wants to have a nurse to help him.

This county has a home delivery nursing service, the first rural area in the United States to have one, we believe. The public health nurses of the Department of Health or of the Red Cross assisted in the delivery of 362 (42.9 per cent) of the 844 residents cared for outside of hospitals. That is a healthy proportion for agencies doing generalized nursing. It is worth noting, however, that a number of women had no one at all to help the doctor at delivery.

The modern physician appreciates the fact that a public health nurse can be of great aid in the education of the patient. How, then, did the public health nurse get in touch with the maternity patient who needed her service? A series of 1,565 cases yielded some information from the Department of Health. The physician himself referred her in 16.3 per cent of the cases. In 4.9 per cent the nurse learned of the pregnancy on a visit for another purpose. In 10.0 per cent the patient herself sent for the nurse, while in 1.5 per cent the nurse was told by the welfare

authorities, and in 4.5 per cent by some other agency or person. In an additional 4.5 per cent the nurse made the contact through some other Health Department service. The largest single source of contact was unfortunately the birth certificate (58.4 per cent). This permits the nurse to be of partial assistance only, but the birth certificate is used by many departments in just this way—to bring the nurse in contact with the new mother.

If the public health nurse can be of service, how soon does she get in contact with the people whom she can help? A sample of 626 cases shows that in 6.5 per cent she called and saw the expectant mother in the first trimester, in 27.8 per cent in the second trimester, and in the remaining 65.7 per cent in the third. This may be compared with 26 per cent, 57 per cent, and 17 per cent in Pike County, Mississippi,⁴ and with 40.5 per cent, 32.2 per cent, and 22.3 per cent in the patients' contacts with the physician.

However, in 22 per cent of a group of 489 women, the public health nurse made her first visit before the patient had registered with a physician. As a matter of fact, a public health nurse called on 13 of the women who never saw a physician before delivery, so that they had had some preparation. Does it matter greatly who sees the patient first, the physician or the nurse? The nurse will urge the patient to see the doctor as soon as possible, and the wise doctor will ask the nurse to call.

Summary

Questionnaires on obstetric care were filled out by cooperating physicians in a high percentage of births in the county during this study. Other information was gathered from nursing practice. Any such self-study reveals achievements of which to be proud and gaps to endeavor to fill. By recognizing these gaps and filling them, we make progress. Substantial numbers still need more prenatal care, and earlier, whether it is care from a physician or education from a nurse. At delivery, conservatism still pays dividends.

The questionnaire is recommended for use as one of the good methods of study. It is better, however, to start tabulation while the study is still in progress.

The results of this study will be made available locally for the use both of the Department of Health and of the Medical Society.

Discussion

Dr. Elizabeth Parkhurst, Albany—Dr. O'Brien has presented a very interesting summary of some of the many factors in obstetric care. His data relating to prenatal care and economic status, particularly, should be useful to the public health administrator. As he stresses in his report, the analysis of the outcome of delivery in a study of this size has the unavoidable limitation of small numbers. Many of the apparent conclusions are of necessity rather tentative and preclude detailed analysis. We have, for instance, the striking statement in Table 4 that the infant mortality among nonoperative deliveries was 5.3 per cent, or almost double the mortality among operative deliveries (2.9 per cent). It is interesting to compare these figures with the neonatal mortality for the entire upstate area, the corresponding information for the mortality among older infants not being readily available. In the last six months of 1940 the neonatal mortality among nonoperative deliveries was practically the same as among operative deliveries: 2.5 and 2.6 per cent. When, however, the rates are based on full-term births only, the nonoperative deliveries show a much lower mortality—1.2 per cent as compared with 1.8 per cent for the operative cases. In other words, since the neonatal mortality among premature infants is more than twenty times that among full-term infants, and the incidence of prematurity, which is about 4 per cent for non-operative cases, varies from less than 2 per cent for midforceps deliveries to 10 per cent for cesarean, any inquiry into infant mortality associated with method of delivery must consider premature and full-term infants separately.

To a worker in the field of public health, one of the main value of studies such as that made in Cattaraugus County lies in the impetus they have given to the state-wide routine collection of pertinent facts regarding complications of pregnancy and labor. In the past this information has had to be secured locally and at considerable cost. When, however, following the pioneer efforts of a number of county medical societies, it became apparent that doctors would welcome active participation by the State Department of Health in a detailed statistical inquiry into the causes of maternal and infant mortality, provision was made on the reverse side of the birth certificate for answers to some of the basic questions with which Dr. O'Brien's report concerned itself. The fact that these optional questions are now answered (gratis!) on more than 90 per cent of the certificates is ample evidence of the realization on the part of the individual medical attendant at a birth that it is only by pooling the observations made by a large section of the profession that the means may be found for the further reduction of the loss of life among mothers and infants.

Dr. Earle G. Brown, Mineola, New York—Dr. O'Brien and the department which he so ably served are to be congratulated on their contribution in this study of the various factors in maternal care which

might have a bearing on infant and maternal mortality. They have emphasized, from the public health point of view, numerous items which prevent or contribute to this mortality:

1. The study is based on data secured from 2,253 resident and 643 nonresident births, or 81 per cent of the 3,562 births reported during a period of two and one-half years. Presumably, follow-up was not made to secure "blue slips" in the remaining number of births. The question naturally arises as to whether or not data on these births would have influenced the total figures.

2. Routine examinations such as urinalysis, blood pressure, and weighing were consistent. One out of 10 patients, however, did not have a pelvic measurement. Possibly the mortality in both infants and mothers may have been higher than in the group that had such measurements.

3. In the case of the rural mother, and in the absence of hospitalization, more reliance was placed in the public health nurse. This demonstrates the need for an intensification of additional trained assistance for the physician at the time of delivery.

4. The need for further intensification of public health nursing service is noted in the "marginal" and "welfare" cases. Whereas, nearly 60 per cent of the cases of "good" economic status received pre-

natal care in the first trimester, this percentage dropped to 29.7 in the "marginal" group and was only 21.2 per cent in the "welfare" group.

5. Of 396 cases, 160 had no postpartum examination, but only 37 patients refused such examination. In 249 cases the patient saw the physician and some examination was made, but in only 10 did this include a pelvic examination. The lack of such examinations demonstrates the need for emphasis in the educational prenatal and postnatal program in order to set up an objective to be achieved by the patient as well as the physician—with the public health nurse as the connecting link.

6. The questionnaire provided an excellent method of making this special study, which otherwise could not have been undertaken. In 70 per cent of the births there was an interval of only one month between the time of birth and the return of the "blue slip." The questionnaire form may be used in other studies but only with the consent of the local medical society.

7. The results of the study will be available not only to the health department staff, but also to local physicians. Without doubt, if a similar study should be made in succeeding years, there would be a marked increase in certain services that could now be considered deficient.

HADASSAH SENDS AID TO PALESTINE

Notified by cable from Jerusalem that Palestine is faced with a threatened shortage of nurses, Hadassah, the Women's Zionist Organization of America, granted an appropriation of \$2,000 out of its war emergency fund to open a new class in the Henrietta Szold School of Nursing in Jerusalem, which is the largest nurses' training school in the country. It is maintained by Hadassah and Junior Hadassah.

The information that more nurses are needed in Palestine to cope with wartime conditions and the request for the immediate training of additional students came from the Hadassah emergency committee in Jerusalem. This will be the first time since the school was opened in 1918 that a midyear class will be begun, according to Mrs. A. P. Schoolman, chairman of the Palestine Committee of Hadassah, who said that trainees will be selected from a waiting list of 320 registrants.

Pointing out that the increase of allied troops, including Americans, in Palestine, and the poor health of recent immigrants necessitate wider medical and health services, Mrs. Schoolman said the Hadassah Medical Organization is doing its utmost to prevent epidemics, and in spite of the scarcity of many foods, "to maintain a high standard of health among the civilian and military population."

The threatened lack of nurses in Palestine, Mrs. Schoolman declared, is due in part to the enlistment of "many hundreds" in the armed forces, serving in Egypt, Syria, Iraq, and other Middle East countries.

A recent survey, Mrs. Schoolman stated, has revealed that more than 1,200 nurses are now on active duty in Palestine, and only 19 nurses are listed as "unemployed." Many of the nurses returned to the profession since the outbreak of the war after taking refresher courses in the Hadassah School. Sixty-five per cent of them are mothers, and to make it possible for them to serve, the Hadassah Medical Organization has established nurseries for the care of their children.

In addition to the undergraduate course, the Henrietta Szold School of Nursing is giving postgraduate courses in health welfare, operating room technic, midwifery, dental and oral hygiene, hospital social service, preventive medicine, and radium technic, and is also training hundreds of volunteer nurses' aides. A number of Polish Red Cross volunteers are being given practical training in the Jerusalem school and in the outpatient department of the Rothschild-Hadassah University Medical Center.

The sum of \$100,000 was cabled to Palestine by Hadassah from New York City in January to provide emergency feeding and to start a long-range program of education for 600 Polish-Jewish refugee children who, after three years of wandering and four months of enforced waiting in camps outside of Teheran, Iran, are now on their way to the Holy Land, where they will be permanently settled. Hadassah announced that the Polish Government-in-Exile had agreed to pay part of the maintenance costs for this group, once they reach Palestine.

THE PRESENT STATUS OF GOLD SALT THERAPY IN EUROPE AND AMERICA IN THE TREATMENT OF CHRONIC ARTHRITIS

R. GARFIELD SNYDER, M.D., and CORNELIUS TRAEGER, M.D., New York City

GOLD therapy has been used in France and England during the past fifteen years, but until seven years ago its use was practically unknown in this country. While American physicians were aware of the enthusiastic reports made by many European rheumatologists on this form of therapy, their willingness to make it available to their patients was to a large extent chilled, or counteracted, when they learned of the frequent occurrence of toxic reactions which often followed the use of gold salts. These toxic reactions vary in degree of severity, but a certain percentage of them are severe, and in a small percentage of cases they may even prove fatal.

Gold therapy is a peculiar and extremely interesting type of treatment, for whenever it is introduced into a country, it invariably arouses bitter controversy among members of the medical profession as to its relative value. The battle still rages with undiminished intensity. In France and England gold therapy is now apparently accepted by the majority of rheumatologists as being the best form of treatment available at the present time for rheumatoid arthritis. In this country gold therapy has not gained general acceptance by the medical profession; it is still on trial. To date, its use does not have the official approval of either the American Rheumatism Association or the American Medical Association.

While this statement is true, it must be admitted that during the past five or six years a gradually but steadily growing interest in the scientific aspects of gold therapy has been perceptible among the various members of the American Rheumatism Association. It is also significant that during the past three years the interest has been greatest among the medical research men of the American Rheumatism Association, who are pooling their efforts to determine how gold acts and how to prevent toxic reactions. As a result of their research, some progress has unquestionably been made, but still many questions concerning gold therapy remain unanswered. These unanswered questions constitute a definite challenge to the research staffs of our great universities.

An attempt will be made in this paper to review the present knowledge of the subject both from an experimental and a clinical viewpoint. At the same time a brief report will be given of our own experience with gold therapy covering a period of seven years.

As early as 1493 the use of gold in the treatment of scurvy was described.¹ Since then many

references to the use of gold in the treatment of tuberculosis and other chronic diseases have appeared in the literature.

It was not until 1929, however, that any report appeared on the use of gold in the treatment of chronic arthritis.

During 1929, Umber,² of Germany, and Forestier,^{3a} of France, both reported on the use of gold compounds in rheumatoid arthritis. Forestier, in 1928, started using gold salts and gave them to practically all his patients who suffered with arthritis during the following five years. The credit for popularizing the administration of gold in rheumatoid arthritis belongs to Forestier, although others have perhaps made more fundamental and critical contributions toward a comprehension of its value.

His first large series of cases with gold salts was published in 1934,^{3b} at which time he reported on the results obtained in treating 500 arthritics. Owing to lack of experience in estimating the initial dose and the maximum single dose, as well as the total dosage for any one series, many severe toxic reactions were unavoidably encountered. A mortality rate of 3 per cent occurred during the first five years of his work. Approximately the same percentage of mortality was later reported by Hartfall and Garland.^{4a}

The results of Forestier's five years' study were as follows: 70 to 80 per cent good results; 40 per cent toxic reactions. It is true that most of the toxic reactions were mild, but 10 per cent were reported to be serious, sometimes lasting several weeks or even months. It should be emphasized that in their early work, the European investigators gave, as an initial dose, from 200 mg. to 500 mg., but later, because of the numerous toxic reactions which developed, the initial dose was reduced to 50 mg. and finally by many workers, including Forestier, even to 10 mg. Forestier's results were confirmed, in general, by many other European workers, including such well-known authorities as Slot,⁵ Buckley,⁶ and Sostberg, Schade, Steuber, and Warburg.⁷

In 1937, Hartfall, Garland, and Goldie,^{4a} of England, published what has since been regarded as a classic and an authoritative review of their results from 900 cases treated over a five-year period.

In our country, Hench,⁸ in the 1939 *Annual Review of Rheumatism*, advised, "any American contemplating the use of gold salts to make a thorough study of Hartfall, Garland, and Goldie's

report before instituting treatment." Their results were as follows: 80 per cent improvement; 46 per cent of the entire group had toxic reactions, 40 per cent of which were mild and 10 per cent serious, and 1 per cent of which resulted in death.

In 1938, Hartfall, Garland, and Goldie^{4b} again reported on 1,200 cases (900 of which were included in their former report), the largest series reported to date. Their results were about the same as those previously reported. However, the importance of this survey was the fact that it included a report on a new gold salt called parmanil. This gold salt, on the whole, was found to be almost as efficacious as myochrysine, but, in their opinion, less toxic.

In regard to the total dose per series, opinions range from 1 Gm. (Hartfall, Garland, and Goldie^{4a}), 1.3 Gm. to 2 Gm. (Forestier^{3b}), to 2.5 Gm. (Bach⁹). Rest periods between series of injections vary from six weeks (Forestier^{3b}), to between two and three months (Hartfall, Garland, and Goldie^{4a}), to six months (Baker¹⁰).

The general consensus of European opinion with regard to the value of gold salt therapy in the treatment of arthritis, after twelve years of experience, is demonstrated by the following quotations: "greatest step forward in therapeutics of arthritis" (Douthwaite, of England¹¹); "results incomparably better than any obtained heretofore, but a dangerous drug" (Stone, of England¹²); "our best and most effective weapon against rheumatoid arthritis, almost 100 per cent effective in the first year, 80 per cent in the second year, and 70 per cent in subsequent years" (Hartfall, Garland, and Goldie, of England^{4b}); "a therapeutic measure of the first order" (Baker, of England¹⁰); "useful in any rheumatic type of arthritis, with proliferative synovial reactions including gonorrheal and tuberculous arthritis" (Bach, of England⁹); "gold salt therapy is quite the most potent now available, but it is attended by not a little risk and should only be undertaken when the case is severe enough to warrant such a very real risk and this should be explained to the patient before treatment is instituted" (Crosby, of England¹³); "I do not like to use gold salts because of the risk of complications" (Willcox, of England¹⁴); "my results so far have been excellent, and the general condition of the patients has been much improved" (Secher, of Denmark¹⁵); "results surpass those of any other therapy, but extremely dangerous" (Van Breemen, of Holland¹⁶).

The general consensus of American opinion up to the time of Forestier's visit to the United States in 1934 was distinctly hostile to the use of gold salts in the treatment of arthritis. The American physicians felt that the European authorities were too enthusiastic in their reports on

the value of gold salt therapy. They could not understand their European colleagues' apparent indifference to and disregard of the high incidence of toxic reactions. It is interesting to note, however, the gradual change in opinion during the past five years. The first statement of American opinion on the use of gold salts was made by Cecil,¹⁷ in 1934, who said: "My experience with gold salts in the treatment of rheumatoid arthritis has been rather limited. Patients whom I have treated by this method have never shown very striking results. Perhaps a larger experience with gold salt therapy might change my opinion." The second American opinion was expressed by Hench in the 1935 *Annual Review of the American Rheumatism Association*, in which he stated that the "Americans were off the gold standard." The following year, the Reviewing Committee of the American Rheumatism Association¹⁸ made the statement that none of the editors had used this method of treatment, but they pointed out that no current treatment for arthritis had a mortality rate of 3 per cent. Therefore, they stated that the results obtained from this type of therapy would have to be unquestionably superior to warrant the risk.

In 1937 the author and his associates presented the first paper on gold therapy read before the American Rheumatism Association. The report was based upon a controlled series of 100 cases; only cases were selected for treatment which had previously proved refractory to every other known form of treatment. In this group 48 per cent of the cases of rheumatoid arthritis showed a definite clinical improvement. For this reason we considered gold therapy a new and valuable treatment if used by those thoroughly conversant with its dangers. The discussion of the paper following its presentation was polite but distinctly skeptical.

In 1938, Keys reported on another carefully controlled series of cases, and to a large extent corroborated our findings. Following Keys' report, gold has been tried out extensively in several of the large university and research clinics in this country with varying degrees of success. In general, the clinical results obtained are the same as those reported in France and England. To date there has been no new method perfected in this country that has proved of definite value in avoiding toxicity or in neutralizing the toxic symptoms that occasionally follow the use of gold therapy once they occur.

Fifteen years of experience in Europe with various gold salts has failed to reveal any marked difference in either the therapeutic or the toxic properties of the various gold salts in common use. It is difficult to compare their action in view of the fact that most of them have a differ-

ent percentage of gold. It is almost impossible to select for comparison or control different series of arthritic patients identical in type and in degree of sensitivity to gold. Included in the list below are the more commonly used gold salts, with their trade and chemical names as well as their gold content.

Name	Content of Gold
Sodium	35%
Gold sodium	37%
Gold sodium	37%
Gold sodium	40%
Solganol B—auro-thio-glucose	44%
Myochrysin—auro-thio-malate of sodium	50%
Aurol-sulfide—Au ₂ S ₃ colloidal gold sulfide	97%

The most commonly used gold salts in America are myochrysin, sancocrysin, solganol B, and aurol-sulfide. Most observers in this country and abroad feel that myochrysin is probably the most effective gold salt, but it also appears to be slightly more toxic than others. The authors prefer to use gold sodium thiosulfate, for, while apparently not quite so efficacious, it has proved to be less toxic in our hands. Most workers report 30 per cent to 40 per cent toxic results with myochrysin, but we have only had 17 per cent toxic reactions with gold sodium thiosulfate. Still others prefer solganol B, but as this is a German preparation, it was not available in this country until recently because of the war.*

The mode of action of gold salts is, to a large extent, unknown. Freyberg¹⁹ has shown that while approximately 30 per cent of the gold is excreted by the kidneys and the intestines, approximately 70 per cent is stored in the tissues of the body. He has also shown that four times as much gold is excreted in the urine as is excreted in the feces. Hartung²⁰ has demonstrated that the kidneys excrete six to seven times as much gold as the intestines. Just how long the gold does stay in the body is uncertain, as it varies with different patients. Freyberg and Hartung have demonstrated that in some of these cases gold was excreted through the kidneys as long as from ninety to three hundred days following the last injection. Recently Freyberg and his associates have demonstrated that gold was still being excreted in one of our cases 509 days after the last injection. They also found gold in the skin of one of our cases, showing a persistent skin

eruption two and a half years after the last injection.

We know that toxic reactions may occur as late as two or three months, or even longer, subsequent to the last dose of gold, and it is because of the danger of these delayed toxic reactions that the question of how long gold remains in the tissues and how long the interval between each series should be has arisen. These questions, obviously, cannot be satisfactorily answered at the present time.

How Does Gold Act?

Feldt²¹ showed that when gold compounds are combined with sulfur compounds, the toxicity of gold is decreased, as evidenced by the fact that when the gold was combined with sulfur, he could administer relatively larger doses to animals without encountering toxic reactions. This apparently was an important and practical contribution to our knowledge of gold therapy, for even up to the present day every gold salt used in the treatment of arthritis contains a certain percentage of sulfur.

From the findings of his experimental work in combining gold and sulfur, Feldt concluded that the beneficial results observed with the use of gold salts in the treatment of streptococcic infections were due to their stimulating effect on the reticulo-endothelial cells. Feldt, Lewy, and Freund²² found that gold salts have no effect on acute streptococcic infections, but, on the other hand, they produced gratifying results upon the chronic streptococcic infections.

According to Koppenhofer,²³ colloidal gold is stored almost exclusively in the reticulo-endothelial cells of the liver, spleen, and bone marrow, and the inorganic gold compounds deposit gold principally in the parenchymal cells, especially in the liver, spleen, and kidneys. This may possibly explain why the inorganic compounds are most active but, unfortunately, much more toxic.

Michelazzi²⁴ found that while gold in small quantities is deposited in the reticulo-endothelial cells of the normal joints, it is deposited in much larger quantities in the same cells where the joints are diseased. This is undoubtedly due to the hypertrophy of the synovial membrane, which always takes place in rheumatoid arthritis, as there are many more endothelial cells found in a diseased joint membrane than are present in a normal joint membrane. These findings have recently been confirmed by Freyberg and his associates in their experimental work done on gold at the Raeburn Research Department of the University of Michigan.¹⁹

Sabin^{25a} has recently demonstrated that he can cure 94 per cent of acute arthritis cases produced by the pleuropneumonia-like organisms in mice

* Myochrysin is supplied by Merck & Co in ampules of 0.05 Gm and 0.10 Gm. Sancocrysin or gold sodium thiosulfate is available from the Abbott Laboratories in ampules containing 10-, 25-, 50-, 75-, 100-, 250-, and 500-mg crystals, which must be dissolved in sterile water just before administration. Solganol B is supplied by Schering in ampules of 10, 25, 50, and 100 mg. Aurol-sulfide is supplied by Hille Laboratories in 25-cc. vials of 1/2, 1, and 2 per cent solutions.

if the animal is treated by myochrysine or gold sodium thiosulfate any time within the first week after the first appearance of arthritic symptoms or physical signs. He can also completely cure a fairly large percentage of these mice if the animal is treated any time within the first month after the first appearance of symptoms or physical signs. At the end of the first month permanent damage is apt to occur in the cartilage and other structures of the joint. Permanent damage cannot be repaired, but subsequent treatment will often prevent further extension of the disease. If it were permissible to assume that we are justified in comparing these animal experiments with human arthritis, Sabin's work would be a good argument for instituting gold therapy early during the first month after the first appearance of arthritis in man. At the present time, though, there is no evidence indicating that any definite relationship exists between human arthritis and that which Sabin has produced in mice. Therefore, the results obtained in the treatment of his experimental arthritis in animals are not applicable to therapy in human arthritis. Many Europeans, however, claim that gold therapy should always be used as early as possible and that results justify the risks.

Dawson²⁶ confirmed Feldt's work, but he differs from Feldt in his conclusions. Whereas Feldt thought that gold acted by a general stimulation of the reticulo-endothelial cells, Dawson is inclined to believe that the chief beneficial effect is due to a direct bacteriostatic effect on a chronic streptococcal infection. He points out that "while the streptococcus has never been proved to be the cause of rheumatoid and infectious arthritis, there is, however, a certain amount of indirect immunologic evidence suggesting that the streptococcus, if not the primary cause, is certainly an important contributing cause. It is not surprising, therefore, that gold salts have a beneficial effect in these two types of arthritis because by their bacteriostatic effect on the streptococci, they may materially aid the patient in overcoming the disease."

Freyberg has recently demonstrated the presence of gold in the synovial fluid aspirated from the joints of patients suffering from rheumatoid arthritis.

Many observers have questioned the contention that metallic gold alone is responsible for beneficial effects. In 1937, two Japanese workers, Yanagesawa and Kawai,²⁷ pointed out that the beneficial results observed from gold salts might be due to the sulfur which they contained, and this contention was somewhat strengthened by Feldt's original discovery that gold worked best in the presence of sulfur. Recently, Freyberg published a report stating that he was unable

to find any evidence of sulfur deficiency or sulfur abnormality among his patients suffering from arthritis. As a result of his findings, Freyberg stated that he believed there was neither a metabolic nor a biochemical indication for sulfur therapy in arthritis, and that for this reason it was reasonable to assume that no possible benefit could be derived by arthritics from its use. These experiments, however, do not successfully explain why it is necessary to have a combination of sulfur with gold in order to obtain a satisfactory, relatively nontoxic substance that can be used with a comparative degree of safety in the treatment of arthritis.

Cumulative clinical experience would seem to indicate that the percentage of gold in any gold salt is a very important factor in producing clinical results. Apparently, the higher the percentage of gold, the better the clinical findings. According to Parr and Shipton, of Australia,²⁸ the only active gold salts are those which contain a high proportion of gold, 40 to 60 per cent combined with a sulfur radical.

Lawrence and Ellman²⁹ treated 40 cases of arthritis, 20 with small doses of gold (100 mg.) and 20 with large doses of gold (200 mg.). They obtained 50 per cent improvement in the cases on large doses of gold, but only 30 per cent improvement in cases on the small doses. This experiment apparently demonstrated the necessity of giving large doses of gold in order to obtain the best therapeutic effect. Lawrence and Ellman also demonstrated an important point—namely, that a large part of the improvement was not due to the psychic effect. They carried out a control series, giving oil in 20 cases, and obtained only 5 per cent improvement.

Toxic Reactions

Upon a thorough review of the literature, it must be admitted that gold salts are of definite therapeutic value, especially in the treatment of rheumatoid or infectious arthritis. Unfortunately, this form of therapy has a very serious drawback because its use is often accompanied by, or later followed by, undesirable toxic reactions. While the majority of these reactions are transient, some are serious, and a very small proportion are even fatal.

The degree of toxic reactions to gold salts is apparently an individual matter. While it is broadly true that large doses given at the beginning of treatment have produced serious toxic reactions, it is also our experience that even minimal doses of gold at the beginning of treatment have produced severe toxic reactions in sensitive patients.

Toxic reactions have occurred from as little as 15 mg. of gold and they have also occurred sev-

eral months after the cessation of the second course. At the present writing, it is permissible to state that there is no period during the entire administration of gold treatment in which one can feel sure that the patient has escaped the danger of toxic manifestations.

In our previous communication³⁰ we published the dosage scheme for the intravenous use of gold sodium thiosulfate in rheumatoid arthritis which over a period of five years has been found to be most efficacious in our hands. We repeat the series schedule here:

1. 5 mg.	6. 75 mg.	11. 100 mg.
2. 10 mg.	7. 100 mg.	12. 100 mg.
3. 15 mg.	8. 100 mg.	13. 100 mg.
4. 35 mg.	9. 100 mg.	14. 100 mg.
5. 50 mg.	10. 100 mg.	990 mg.

The consensus of the great majority of rheumatologists is that an interval of at least two months should be allowed between the first and second courses. It is generally agreed that patients should always have at least two courses of treatment, whether or not the results following the first series have been considered satisfactory. If steady improvement is obtained, it might be wise to go on with further treatment. If no improvement is shown at the end of three courses, the treatment should be discontinued.

During the past two years a new gold salt has appeared on the market in England. It is called parmanil and was first used by Hartfall, Garland, and Goldie.⁴⁹ In a series of 50 cases, they reported 26 per cent toxic reactions and almost as good clinical results as with myochrysin. Although this represents a drop of almost 15 per cent in the percentage of their toxic reactions, unfortunately they still obtained almost the same percentage of serious toxic reactions (6 per cent) as they did with the more active gold salt. However, they did not report any deaths in this particular series, whereas they reported 1 per cent in their previous series in which myochrysin was used in most of the cases treated.

In our first series of 100 cases of chronic arthritis treated by the intravenous use of gold sodium thiosulfate, we reported only 17 per cent toxic reactions, or approximately one half the percentage of toxic reactions one would expect to see following the use of myochrysin. During the past three years, in spite of exercising all the precautions previously referred to in this article, we have not succeeded in further reducing this percentage. Our percentage of definite clinical improvement continued to be approximately the same as that of our first series, which was 48 per cent. This percentage of improvement is not so high as that reported by most other authorities,

but it should be remembered that our report was based on cases studied over a two-year period—cases which had previously proved refractory to most of the commonly accepted forms of treatment. It is true that we have succeeded in lowering the percentage of our serious toxic reactions to 3 per cent. But while this is gratifying, since most writers both here and abroad state that they see approximately 6 per cent serious toxic reactions, even 3 per cent serious toxic reactions is still too high a figure. In 1 per cent of the cases reported in the literature, a fatality has occurred, and probably all fatalities are not reported.

As yet, there is no known method of avoiding toxic reactions. By starting with small doses and keeping the first few doses at the same level, the percentage of toxic reactions seems to be decreased. It has been claimed recently by Secher, however, that in a series of 150 cases of arthritis treated by him, all toxic reactions were eliminated by the administration of four times the normal requirements of vitamins B₁, B₂, C, and D. The accuracy of these findings should be checked in the large arthritic clinics in this country.

Parr and Shipton⁵² report that women are eight times more susceptible to toxic reactions from gold salts than are men. This emphasizes the extreme importance of being particularly careful in administering gold salts to women.

In our clinic at the Hospital for Special Surgery we have never used gold salts in early cases of arthritis. It seems justifiable, however, in spite of the danger of toxic reactions, to try the gold salts injections in those cases in which all other previous therapy has failed. Even in such cases, the danger of the treatment should be thoroughly explained to the patient. It should be emphasized at the same time that failure to check the disease may result in a "wheel chair" existence, and that consequently a certain amount of risk is justified. The doctor should have the patient sign a release from any legal responsibility in regard to any toxic reactions that might occur.

Colloidal Gold

As to the relative therapeutic efficacy of colloidal versus crystalloid metals, much still remains to be learned. Owing to the claim that they are nontoxic, we felt that it might be wise to test, in cooperation with several other clinics, the relative efficiency as well as the degree of toxicity of the safer colloidal salts, particularly in cases that had previously proved to be sensitive to the inorganic gold salts.

In so far as our own experience with aurolsulfide is concerned, we obtained, out of 28 cases treated in the clinic, one apparent cure and 10 cases of partial improvement. However, we found that, although it was less toxic, it was not

effective enough in our opinion to warrant its use in refractory cases of arthritis. In these difficult cases, if gold is used as a final resort, it is justifiable to use the gold compounds that are known to be most effective even if they are slightly more toxic.

In regard to the degree of toxicity, auro-sulfide is definitely less toxic than myochrysine and gold sodium thiosulfate, but, in fairness to these older products, it should be pointed out that auro-sulfide is also apparently much less effective. In our series of 28 cases we had only three minor toxic reactions with one skin eruption which lasted two months, and we had no serious reaction. In our first experiment with auro-sulfide we used from 1 to 5 cc. of a 1 per cent solution only and gave this intravenously. In these doses we had no toxic reactions, but we observed no clinical improvement. We finally obtained a 2 per cent solution and gave this in doses of from 5 to 10 cc. intravenously and then, as the dosage increased, we began to observe a corresponding degree of improvement in the clinical results observed. In contrast to our clinical findings, Sabin's report is that he observed no clinical improvement in his mice suffering from experimentally produced arthritis following the intravenous use of auro-sulfide. Freyberg¹⁹ has recently reported that he could find no trace of auro-sulfide in the blood stream of his patients a few seconds after a single dose of as much as 6 cc. of a 2 per cent solution had been injected intravenously. It is true that Freyberg did not test the blood for gold after 10 cc. of auro-sulfide had been given at one dose; neither did he test it after the dose had been repeated several times. We do know that auro-sulfide is rapidly removed from the blood stream and deposited in the reticulo-endothelial cells. Whether this produces a beneficial or a harmful effect has not yet been determined.

During the panel discussion on arthritis at the 1941 meeting of The American College of Physicians and Surgeons in Boston, Dr. Walter Bauer, of the Massachusetts General Hospital, insisted that the case for gold salt therapy in arthritis was not yet proved. He pointed out that in a survey of 1,800 cases reported in the literature as having been treated by gold salts, toxic complications occurred once in every 30 cases and a mortality once in every 200 cases. He also pointed out that, except for two series,* in this country there has been no well-controlled study of results of gold therapy in arthritis. He emphasized, too, that, in all but a very few series, the percentage of improvement presented in the

literature in support of gold therapy did not differ materially from those obtained at the Massachusetts General Hospital with rheumatoid arthritics who received six to eight months of good general hospital care and the ordinarily accepted safer methods of treatment.

Dr. Sabin²⁰ has recently been treating his mice suffering from arthritis produced by the pleuropneumonia-like organism with a new insoluble organic compound called "calcium aurothioglycolate" and has found that while it apparently is nontoxic when given in the maximum doses that can be administered to a mouse, it nevertheless exercised a striking curative effect on this type of acute arthritis in mice. Up to the present time nothing has appeared in the literature by Sabin or other workers to report whether or not this salt is nontoxic to the human being who suffers from arthritis. Neither have we any reports concerning its curative effects on acute rheumatoid arthritis in man.

The authors, therefore, feel that auro-sulfide and other colloidal gold salts, as well as calcium aurothioglycolate, will have to be tested much more extensively in this country before we can get any true appreciation of their therapeutic value in comparison with that of the other organic and inorganic gold salts that have been found, to date, to be efficacious, but sometimes toxic, in the treatment of arthritis.

Conclusions

1. Gold salt therapy has been found to be effective in cases of rheumatoid, infectious and mixed forms of arthritis which have failed to respond to other types of treatment. In our experience during the past five years, we found that gold salts were helpful in 48 per cent of our rheumatoid cases.

2. A survey of the literature on gold salts reveals that experienced rheumatologists have found gold salts to be an effective weapon in handling rheumatoid arthritis.

3. Gold salt therapy is dangerous because of its toxic reactions. The percentage of toxicity ranges from 16 per cent to 40 per cent. These toxic reactions seem to depend in part upon the type of gold salt used, as well as upon the patient's susceptibility.

4. In the use of gold salts, every effort should be made to minimize the possibility of toxic reactions. It is urged that the patient be watched carefully for early signs of reactions and that caution be exercised in determining the amount of the dosage.

5. Although some authors advise that gold should be used early in the treatment of arthritis, we believe that other less dangerous forms of therapy should be utilized first.

* These two series included 53 cases by Dr. Keys of St. Louis and our own cases. In both these series, cases were used in which all previous attempt at treatment had failed.

NURSING SCHOOLS SEEK 1,000 STUDENTS FOR FEBRUARY CLASSES

An intensive campaign to persuade college girls to undertake nursing as a career will be carried on during the next few weeks by the New York City Nursing Council for War Service, 654 Madison Avenue, among college and university students, it has been announced by Miss Mary Burr, executive secretary of the Council.

"The need for greatly increasing the number of student nurses has never been so urgent as it is right now," Miss Burr emphasized, in making public an appeal to college girls and high-school seniors to give serious consideration to nursing as a field of "war work with a peacetime future."

An effort is being made to recruit 1,000 students for the new classes beginning in February in thirty-two schools of nursing in New York City, Westchester County, and Long Island; the quota for nursing schools throughout the United States is 19,000.

As part of the recruiting drive, groups of college girls are being taken on tours of local hospital schools of nursing and to view an exhibit on display

at headquarters of the Henry Street Visiting Nurse Service, 262 Madison Avenue.

Although particular emphasis is being placed on the recruiting of college girls, Miss Burr said, an academic high-school diploma is sufficient for admission to the February classes of the schools of nursing in New York City; a year or more of college, however, is considered valuable additional training. An increasing number of executive, teaching, and research opportunities will be available in the postwar reconstruction period for women who combine college and nursing education, Miss Burr predicted.

Girls entering schools of nursing must be between the ages of 18 and 35. Although the basic course takes three years to complete, extra credit resulting in shorter courses is now being given to students entering with college degrees.

Mrs. Langdon P. Marvin is president of the New York City Nursing Council for War Service, and Miss Eleanor Lee is chairman of the recruiting committee.

FOOD CHARTS

A twenty-page pamphlet entitled "Food Charts—Foods as Sources of the Dietary Essentials" has just been prepared by a joint committee of the Council on Foods and Nutrition of the American Medical Association and of the Food and Nutrition Board of the National Research Council. The charts are interesting and useful in that they show at a glance the proportion of the daily allowance provided by a selected serving of food. They should be valuable to those interested in teaching and in the application of practical nutrition. Included are the tables

of "Recommended Dietary Allowances" and of "Minimum Dietary Requirements." Written material accompanies each chart concerning the vitamin A, thiamine, riboflavin, niacin, ascorbic acid, protein, calcium, and iron contents of the common foods.

It is planned to print a large number of these pamphlets, and the cost will be covered by a small charge. Address: Council on Foods and Nutrition, American Medical Association, 535 North Dearborn Street, Chicago, Illinois.—*Health News*

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the March 1 issue and will concern "Recent Advances in Sulfonamide Therapy."

The Management of Peptic Ulcer: II. Surgical Aspects

DR. WILLIAM DEW. ANDRUS: Having considered the medical aspects of peptic ulcer at the last conference, we are to take up today some of the surgical aspects of treatment.

The surgical treatment of peptic ulcer is essentially the treatment of its complications. On that point I think everyone is fairly well agreed. Differences of opinion arise, however, as to the application of surgery to particular complications, both as to the time when it should be applied and as to the method which should be used.

Dr. Cooper will consider certain of the complications of ulcer.

DR. WILLIAM A. COOPER: The treatment of the complications of peptic ulcer comprises a large subject.

By far the most common complication of peptic ulcer is penetration, which is to be distinguished from free perforation. It is characterized by marked and protracted ulcer pain, which fails to respond to the usual dietary measures, and, indeed, may not respond to any form of conservative treatment. Such an ulcer requires surgery when medical treatment has failed.

There are three operations which are commonly used—namely, gastro-enterostomy, gastro-enterostomy with excision of the ulcer, and gastric resection. There is some controversy as to which of these is preferable, but in recent years there has been a trend toward doing more gastric resections on such cases.

If a penetrating ulcer progresses, it may lead to the second complication—namely, a free perforation, particularly if the ulcer is on the anterior portion of the duodenum or in the stomach. The clinical picture is characterized by sudden onset of severe upper abdominal pain rapidly progressing to involve the entire abdomen, circulatory shock, and the classical boardlike rigidity of the abdomen. Such an occurrence, of course, leads to the development of peritonitis, and requires immediate operation. It should be emphasized that the mortality of the perforated ulcer is directly proportional to the time interval

between the perforation and operation. In the operative treatment there is again a choice of procedures—simple plication of the ulcer, plication and gastro-enterostomy or gastric resection. Since the majority of these patients are seriously ill, the lesser procedure is usually the one of choice—namely, simple plication of the ulcer.

The third complication is hemorrhage, which Dr. Holman will discuss.

The fourth complication is obstruction. Obstruction most commonly occurs in duodenal ulcers but may also occur in a gastric ulcer which is obstructing the pylorus, or in an ulcer anywhere along the lesser curvature associated with reflex spasm of the pylorus. Obstruction is characterized by vomiting quantities of food eaten many hours previously. Obstruction due to reflex spasm of the pylorus associated with an ulcer on the lesser curvature usually responds to dietary measures and does not require surgery for the obstruction *per se*. Obstruction at the distal end of the pylorus due to a lesion at that site is usually due to cancer and not ulcer, so the operative treatment is gastric resection in one or two stages, depending upon the condition of the patient. Duodenal ulcer is the most common obstructing ulcer and requires operation. Again there is a choice of gastro-enterostomy or gastric resection, but this type is most likely to do well with the simpler procedure, gastro-enterostomy.

The fifth and last complication of ulcer is malignant degeneration. Strangely, in spite of the frequency of duodenal ulcer, malignant degeneration at this site is so rare that it need not be considered clinically. Since duodenal ulcer and gastric cancer are so infrequently observed together—only once in the experience of the New York Hospital—it is possible that the presence of a duodenal ulcer may protect the patient against the development of gastric cancer. In gastric ulcer the possibility of malignant degeneration must be considered. Just how frequently gastric ulcer becomes gastric cancer will probably never be known definitely. It is likely that this is not

very common, and the figure is less than 5 per cent. Yet in every gastric lesion which looks like an ulcer on x-ray, cancer must be considered, and the number that are cancer is well over 5 per cent. For this reason the gastric ulcer presents a very different problem from the duodenal ulcer. Gastric lesions away from the lesser curvature are almost always cancer. The ones near the pylorus are about 90 per cent cancer, and as one proceeds above the pylorus the incidence of cancer decreases.

Clinical examination fails to distinguish gastric ulcer from gastric cancer that looks like ulcer. The x-ray examination is only about 75 per cent accurate in differentiating one from the other. The gastric analysis has its exceptions. The naked eye is fallible, and the gastroscope is likewise fallible. In fact, the only reliable differentiator is the microscopic section.

For practical purposes, then, we must have a set of rules to guide us in the treatment of gastric ulcer. Probably the safest rule is to do a gastric resection on any gastric ulcer which fails to heal and remain healed after, at most, five or six weeks of medical treatment. This does not mean that the recurrent lesion should be given another five or six weeks, for the recurrence may very rapidly grow into inoperable cancer.

Now I will give you a few figures on the incidence of these various complications in the New York Hospital series. These figures comprise a summary of the entire experience of the cases admitted to the hospital, on both the medical and surgical services, from 1932 through 1939. Total cases, 885; duodenal ulcer, 718; gastric ulcer, 172; now dead, 103; cases operated upon, 339; operative deaths, 26 (7%).

As you see, the total number of cases is 885, so ulcer is a pretty common disease. They are divided into 718 duodenal ulcers and 172 gastric ulcers, a ratio of about 5 to 1. You will obtain some concept of how serious the complications of ulcer are, for about 103, or about 12 per cent, of the 885 patients are now known to be dead.

As to the distribution of the various complications, penetrating ulcers, of course, comprised a large percentage of the ulcers that were admitted to the hospital. It must be remembered that there were many times 885 cases seen in the outpatient department, and only those that did poorly in the outpatient department were admitted to the hospital. It is likely that well over half of this number, therefore, had some element of penetration or marked activity of the ulcer. There were 85 cases (9.6 per cent) of perforated ulcer, that is free perforation into the peritoneal cavity. There were 170 cases (19 per cent) in which bleeding was a marked symptom, and there were 80 cases (9 per cent) in which obstruction was a prom-

inent feature of the lesion. There were many more cases in which the obstruction was not marked. The number which had carcinoma-degeneration I am unable to give you because that is a controversial question which is difficult to decide in each individual case. However, in a few cases it seems certain that there was carcinomatous degeneration in a gastric ulcer of long standing.

The distribution of operative procedures was as follows: Posterior gastro-enterostomy was done in 172 of the 885 cases; the operative mortality was 4.6 per cent. Gastric resection was done on 162 cases and most of these, I might add, were done in the last four years; the operative mortality of resection was 8 per cent, almost twice that of gastro-enterostomy. Most of the 85 perforated ulcers had a simple plication; the mortality was 7 per cent. Excision and posterior gastro-enterostomy was done on relatively few (13 cases), with no operative mortality. Of the secondary gastric operations there were 32 cases, with a mortality of 12.5 per cent.

The results of these operations are of particular interest, for it is through observation of cases for a long period after operation that we have learned so much about peptic ulcers. The observations have emphasized the constitutional factors in peptic ulcers, for new ulcers have formed in patients in whom the old ulcer was removed. They have also taught surgeons to resort to operative treatment with some caution, for secondary operations on the stomach are not as simple as the primary procedures.

Let us first consider the results of gastro-enterostomy, which was done on about 20 per cent of all the cases admitted to the hospital. Of those having gastro-enterostomy, 12 per cent are now known to be dead. About half of the deaths were due to causes other than ulcer. About 70 per cent have had a good result, with no serious recurrence of ulcer symptoms. Another 8 per cent have been greatly improved but have had one or more recurrent attacks which prevent their being classified as a good result. Another 8 per cent have had recurrent ulcers of a serious nature, most of them marginal ulcers. About 3 per cent have required further operative treatment. Two per cent have been lost. The best results of gastro-enterostomy were in the older patients having obstruction.

The results of gastric resection are a little better, but it is to be noted that the improved results are largely due to the absence of poor results from marginal ulcer. Good results have been noted in 72 per cent of the cases, while 14 per cent are greatly improved. Two per cent have a poor result but are living, and 2 per cent are lost. Ten per cent are now dead—2 per cent owing to causes other than ulcer. Comparison

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the March 1 issue and will concern "Recent Advances in Sulfonamide Therapy."

The Management of Peptic Ulcer: II. Surgical Aspects

DR. WILLIAM DEW. ANDRUS: Having considered the medical aspects of peptic ulcer at the last conference, we are to take up today some of the surgical aspects of treatment.

The surgical treatment of peptic ulcer is essentially the treatment of its complications. On that point I think everyone is fairly well agreed. Differences of opinion arise, however, as to the application of surgery to particular complications, both as to the time when it should be applied and as to the method which should be used.

Dr. Cooper will consider certain of the complications of ulcer.

DR. WILLIAM A. COOPER: The treatment of the complications of peptic ulcer comprises a large subject.

By far the most common complication of peptic ulcer is penetration, which is to be distinguished from free perforation. It is characterized by marked and protracted ulcer pain, which fails to respond to the usual dietary measures, and, indeed, may not respond to any form of conservative treatment. Such an ulcer requires surgery when medical treatment has failed.

There are three operations which are commonly used—namely, gastro-enterostomy, gastro-enterostomy with excision of the ulcer, and gastric resection. There is some controversy as to which of these is preferable, but in recent years there has been a trend toward doing more gastric resections on such cases.

If a penetrating ulcer progresses, it may lead to the second complication—namely, a free perforation, particularly if the ulcer is on the anterior portion of the duodenum or in the stomach. The clinical picture is characterized by sudden onset of severe upper abdominal pain rapidly progressing to involve the entire abdomen, circulatory shock, and the classical boardlike rigidity of the abdomen. Such an occurrence, of course, leads to the development of peritonitis, and requires immediate operation. It should be emphasized that the mortality of the perforated ulcer is directly proportional to the time interval

between the perforation and operation. In the operative treatment there is again a choice of procedures—simple plication of the ulcer, plication and gastro-enterostomy or gastric resection. Since the majority of these patients are seriously ill, the lesser procedure is usually the one of choice—namely, simple plication of the ulcer.

The third complication is hemorrhage, which Dr. Holman will discuss.

The fourth complication is obstruction. Obstruction most commonly occurs in duodenal ulcers but may also occur in a gastric ulcer which is obstructing the pylorus, or in an ulcer anywhere along the lesser curvature associated with reflex spasm of the pylorus. Obstruction is characterized by vomiting quantities of food eaten many hours previously. Obstruction due to reflex spasm of the pylorus associated with an ulcer on the lesser curvature usually responds to dietary measures and does not require surgery for the obstruction per se. Obstruction at the distal end of the pylorus due to a lesion at that site is usually due to cancer and not ulcer, so the operative treatment is gastric resection in one or two stages, depending upon the condition of the patient. Duodenal ulcer is the most common obstructing ulcer and requires operation. Again there is a choice of gastro-enterostomy or gastric resection, but this type is most likely to do well with the simpler procedure, gastro-enterostomy.

The fifth and last complication of ulcer is malignant degeneration. Strangely, in spite of the frequency of duodenal ulcer, malignant degeneration at this site is so rare that it need not be considered clinically. Since duodenal ulcer and gastric cancer are so infrequently observed together—only once in the experience of the New York Hospital—it is possible that the presence of a duodenal ulcer may protect the patient against the development of gastric cancer. In gastric ulcer the possibility of malignant degeneration must be considered. Just how frequently gastric ulcer becomes gastric cancer will probably never be known definitely. It is likely that this is not

fifteen years it has become more and more popular. Polya reported that about 260 types of gastric resection have been employed so far. This probably means that none of them is uniformly effective in reducing acidity, and that has also been our experience to a limited extent.

We have found that the postoperative acidity varies with the type and the degree of resection. We find that in approximately 90 per cent of the group of patients in whom merely the antrum is removed, there is still considerable acid after the operation. If the resection is extended up beyond the re-entrant angle on the lesser curvature, the acidity of the stomach is greatly diminished in about 85 per cent of the cases. Not all these patients are anacid, but the acidity is so low that it is difficult to measure. Recently, some surgeons have been advocating larger and larger resections, but it would seem impracticable for the general surgeon to extend the resection extremely high and still keep the mortality low enough for this operation to be used safely in the treatment of ulcer.

In the postoperative physiology of the stomach, acidity is only one factor. The reason this has always enjoyed the most attention is that it is the easiest one to examine and study. It is very difficult to study the postoperative motility of the stomach, which is probably as important a factor in causing symptoms as is the acidity, if not the most important factor in causing ulcer symptoms.

Dr. ANDRUS: There are a few comments I should like to make at this point. One is that the total number of 386 operations in the 885 ulcer cases summarized by Dr. Cooper is not excessive. It indicates a reasonably conservative attitude on the part of the surgeons.

Dr. Cooper neglected to mention specifically one group of cases of perforation which we ordinarily refer to as subacute as distinguished from penetration and free perforation. In that group we include the cases in which perforation occurs so slowly that it is walled off or those in which, because of the location of the ulcer, there is perforation in the lesser sac or in the region of the omentum rather than free into the general peritoneal cavity from the small space on the anterior surface of the duodenum and pyloric end of the stomach. In this situation the liver moves up and down with respiration and so tends to diminish the likelihood of walling off a perforation.

Dr. Holman, in speaking of the regimen for bleeding, did not specifically detail what the conservative treatment is, and I believe that it differs considerably on the medical and surgical services. In general our tendency on the surgical service is not to feed these patients, certainly not to feed them early in their course in the hospital,

whereas I think the medical service is coming more and more to adopt a policy of feeding. Perhaps someone from the medical service would like to discuss the treatment of bleeding ulcers from this angle.

Dr. C. H. WHEELER: The routine which we have employed on the medical service for the last two or possibly three years is to feed all cases of bleeding ulcer from the very beginning. The feedings consist of the routine Sippy regimen with the addition of various types of soft food including milk-toast, custard, junket, smooth cooked cereals, and pureed vegetables. A good many of us who were in the hospital in the days when we used to starve the patients and treat them with parenteral fluid for a period of time, as is done now in the surgery pavilion, feel that since we have been feeding them, the results are better than when nothing was given by mouth. The patients seem to get more prompt relief of pain, the bleeding seems to stop just as quickly, and finally—and this is certainly important—their stay in the hospital and the time required to bring their blood counts back within normal limits appear to be greatly shortened.

One important point which should be emphasized in this connection is that an appreciable percentage of patients with bleeding ulcer are perforating or have perforated when they come into the hospital. Before starting to feed a patient with a bleeding ulcer, one should feel sure that it has not perforated, or is not about to perforate, because if such is the case, naturally one would not think of giving food.

There seems to be evidence accumulating in the literature from both medical and surgical sources that the method of feeding is as good, if not better, than the starvation regimen. That was first pointed out by Meulengracht in Sweden, whose figures Dr. Holman quoted as the best which have been published.

STUDENT: I would like to ask Dr. Wheeler how he determines which cases are about to perforate or penetrate?

Dr. WHEELER: Such a case might be one with a history of unusually severe and persistent pain, particularly marked tenderness on abdominal palpation, undue fever or leukocytosis, or the finding of penetration in recent roentgenologic studies of the gastrointestinal tract. In addition, of course, there are the patients who present the findings of frank perforation, such as boardlike rigidity of the abdomen.

Dr. ANDRUS: I know of no field in which there is legitimate ground for such radical differences of opinion as in the management of the bleeding ulcer, and I must confess to changing my own opinion from time to time, as I think we are all apt to do, on the basis of spectacular cases.

of the results of the two operations in this manner is not entirely fair to either operative procedure, for there is careful selection of cases that unquestionably affects the end results of both gastro-enterostomy and gastric resection.

Excision of the ulcer and gastro-enterostomy is not widely used in this hospital. The procedure is applicable only in a selected group of cases, and indeed, has been done but 13 times. The results are good in 11 of the 13 cases, but the other 2 have developed new ulcers.

In treating perforated ulcers by simple plication, one can keep the mortality below 10 per cent, but about half of these people will have recurrent ulcer symptoms, and some will require further surgery.

This constitutes a superficial review of our experience in the treatment of the complications of peptic ulcer. Suffice it to say that more detailed analyses are available. From these we have learned that surgery is to be resorted to with caution, but not with stubbornness, and that the choice of procedure in each individual case is most important.

DR. ANDRUS: Dr. Holman will speak about hemorrhage as a complication of ulcer, and I hope will introduce some of his studies on the effects of operation on certain aspects of the physiology of the stomach.

DR. CRANSTON HOLMAN: Opinion as to the best treatment of massive hemorrhage in peptic ulcer varies so greatly that a discussion of the subject seldom fails to end in controversy. The decision as to what type of therapy is indicated should take into consideration several factors: It is well established that most patients with bleeding ulcer recover under any form of conservative therapy and the best recorded results are those of Meulengracht and Hurst, who report a mortality of 1 per cent and 5 per cent, respectively. Unfortunately, other clinics have not had so favorable an experience, and at the New York Hospital where until recently all patients admitted because of massive hemorrhage were treated conservatively, two or three patients died each year as a result of the bleeding. In many of these cases a large eroded artery at the base of the ulcer was found, usually the pancreaticoduodenal artery, and it is unlikely that anything but a direct attack upon this bleeding point could have saved the patient. The mortality in bleeding ulcer is also influenced by age and sex. In our group it was 7 per cent for patients under 40, in contrast to 17 per cent for those over 40. Generally speaking, bleeding ulcer is more hazardous in men than in women.

In considering operative therapy it should be remembered that the operative mortality is relatively high in patients who are bleeding rap-

idly from an ulcer. Finsterer has shown that one way to reduce the high operative mortality is to operate early in the course of the hemorrhage, and he reports a mortality of only 5 per cent when immediate operation is the rule. That figure is undoubtedly too low or too optimistic for all of us to accept as to what might be expected from the general surgeon operating on a large group of patients. However, we may assume that possibly the mortality may be kept down to between 10 or 15 per cent with operation.

In summary, then, we recommend that conservative therapy be used routinely for patients with bleeding ulcer. There is, however, a group of patients who fail to respond to this therapy and will die if it is continued.

In selecting those patients with bleeding ulcer for operation, there are several guides which may be followed with advantage: Operate on the patient who starts bleeding during the course of conservative therapy in the hospital. We had 6 patients who started to bleed under these conditions. Five of them died when the conservative therapy was continued. The sixth patient was operated on and made a satisfactory recovery. Also, operate on the patient who has continuous or repeated bleeding during the first 48 to 72 hours after hospitalization, since in patients with prolonged bleeding the mortality approximates 50 per cent in contrast to 5 per cent for those who respond immediately and satisfactorily to conservative therapy.

When a patient is operated on, a direct attack upon the bleeding point should be made, and the easiest way to do this is to perform a small or moderate sized resection. Neilson has shown the inadequacy of lesser procedures, such as gastrostomy, gastro-enterostomy, and plastic procedures on the duodenum.

In accounting for the good and bad results in operations for peptic ulcer, the matter of gastric acidity has received a great deal of attention. Gastro-enterostomy was first introduced for the treatment of obstruction but was later used in an endeavor to reduce gastric acidity in ulcer patients. It usually fails to do this. In approximately 90 per cent of our group of patients the gastric acidity was not affected. Statements regarding gastric acidity need to be taken with some reservation, in view of the difficulties of doing satisfactory gastric analyses on patients with operative procedures. Frequently 4 or 5 gastric analyses on the same subject are necessary before a true reading is obtained.

Because of the failure of gastro-enterostomy to effect a diminution in gastric acidity, and because of the large number of marginal ulcers which have been reported following this operation, gastric resection was introduced. During the past

of the results of the two operations in this manner is not entirely fair to either operative procedure, for there is careful selection of cases that unquestionably affects the end results of both gastro-enterostomy and gastric resection.

Excision of the ulcer and gastro-enterostomy is not widely used in this hospital. The procedure is applicable only in a selected group of cases, and indeed, has been done but 13 times. The results are good in 11 of the 13 cases, but the other 2 have developed new ulcers.

In treating perforated ulcers by simple plication, one can keep the mortality below 10 per cent, but about half of these people will have recurrent ulcer symptoms, and some will require further surgery.

This constitutes a superficial review of our experience in the treatment of the complications of peptic ulcer. Suffice it to say that more detailed analyses are available. From these we have learned that surgery is to be resorted to with caution, but not with stubbornness, and that the choice of procedure in each individual case is most important.

DR. ANDRUS: Dr. Holman will speak about hemorrhage as a complication of ulcer, and I hope will introduce some of his studies on the effects of operation on certain aspects of the physiology of the stomach.

DR. CRANSTON HOLMAN: Opinion as to the best treatment of massive hemorrhage in peptic ulcer varies so greatly that a discussion of the subject seldom fails to end in controversy. The decision as to what type of therapy is indicated should take into consideration several factors: It is well established that most patients with bleeding ulcer recover under any form of conservative therapy and the best recorded results are those of Meulengracht and Hurst, who report a mortality of 1 per cent and 5 per cent, respectively. Unfortunately, other clinics have not had so favorable an experience, and at the New York Hospital where until recently all patients admitted because of massive hemorrhage were treated conservatively, two or three patients died each year as a result of the bleeding. In many of these cases a large eroded artery at the base of the ulcer was found, usually the pancreaticoduodenal artery, and it is unlikely that anything but a direct attack upon this bleeding point could have saved the patient. The mortality in bleeding ulcer is also influenced by age and sex. In our group it was 7 per cent for patients under 40, in contrast to 17 per cent for those over 40. Generally speaking, bleeding ulcer is more hazardous in men than in women.

In considering operative therapy it should be remembered that the operative mortality is relatively high in patients who are bleeding rap-

idly from an ulcer. Finsterer has shown that one way to reduce the high operative mortality is to operate early in the course of the hemorrhage, and he reports a mortality of only 5 per cent when immediate operation is the rule. That figure is undoubtedly too low or too optimistic for all of us to accept as to what might be expected from the general surgeon operating on a large group of patients. However, we may assume that possibly the mortality may be kept down to between 10 or 15 per cent with operation.

In summary, then, we recommend that conservative therapy be used routinely for patients with bleeding ulcer. There is, however, a group of patients who fail to respond to this therapy and will die if it is continued.

In selecting those patients with bleeding ulcer for operation, there are several guides which may be followed with advantage: Operate on the patient who starts bleeding during the course of conservative therapy in the hospital. We had 6 patients who started to bleed under these conditions. Five of them died when the conservative therapy was continued. The sixth patient was operated on and made a satisfactory recovery. Also, operate on the patient who has continuous or repeated bleeding during the first 48 to 72 hours after hospitalization, since in patients with prolonged bleeding the mortality approximates 50 per cent in contrast to 5 per cent for those who respond immediately and satisfactorily to conservative therapy.

When a patient is operated on, a direct attack upon the bleeding point should be made, and the easiest way to do this is to perform a small or moderate sized resection. Neilson has shown the inadequacy of lesser procedures, such as gastrostomy, gastro-enterostomy, and plastic procedures on the duodenum.

In accounting for the good and bad results in operations for peptic ulcer, the matter of gastric acidity has received a great deal of attention. Gastro-enterostomy was first introduced for the treatment of obstruction but was later used in an endeavor to reduce gastric acidity in ulcer patients. It usually fails to do this. In approximately 90 per cent of our group of patients the gastric acidity was not affected. Statements regarding gastric acidity need to be taken with some reservation, in view of the difficulties of doing satisfactory gastric analyses on patients with operative procedures. Frequently 4 or 5 gastric analyses on the same subject are necessary before a true reading is obtained.

Because of the failure of gastro-enterostomy to effect a diminution in gastric acidity, and because of the large number of marginal ulcers which have been reported following this operation, gastric resection was introduced. During the past

fifteen years it has become more and more popular. Polya reported that about 260 types of gastric resection have been employed so far. This probably means that none of them is uniformly effective in reducing acidity, and that has also been our experience to a limited extent.

We have found that the postoperative acidity varies with the type and the degree of resection. We find that in approximately 90 per cent of the group of patients in whom merely the antrum is removed, there is still considerable acid after the operation. If the resection is extended up beyond the re-entrant angle on the lesser curvature, the acidity of the stomach is greatly diminished in about 85 per cent of the cases. Not all these patients are anacid, but the acidity is so low that it is difficult to measure. Recently, some surgeons have been advocating larger and larger resections, but it would seem impracticable for the general surgeon to extend the resection extremely high and still keep the mortality low enough for this operation to be used safely in the treatment of ulcer.

In the postoperative physiology of the stomach, acidity is only one factor. The reason this has always enjoyed the most attention is that it is the easiest one to examine and study. It is very difficult to study the postoperative motility of the stomach, which is probably as important a factor in causing symptoms as is the acidity, if not the most important factor in causing ulcer symptoms.

DR. ANDRUS: There are a few comments I should like to make at this point. One is that the total number of 386 operations in the 885 ulcer cases summarized by Dr. Cooper is not excessive. It indicates a reasonably conservative attitude on the part of the surgeons.

Dr. Cooper neglected to mention specifically one group of cases of perforation which we ordinarily refer to as subacute as distinguished from penetration and free perforation. In that group we include the cases in which perforation occurs so slowly that it is walled off or those in which, because of the location of the ulcer, there is perforation in the lesser sac or in the region of the omentum rather than free into the general peritoneal cavity from the small space on the anterior surface of the duodenum and pyloric end of the stomach. In this situation the liver moves up and down with respiration and so tends to diminish the likelihood of walling off of a perforation.

Dr. Holman, in speaking of the regimen for bleeding, did not specifically detail what the conservative treatment is, and I believe that it differs considerably on the medical and surgical services. In general our tendency on the surgical service is not to feed these patients, certainly not to feed them early in their course in the hospital,

whereas I think the medical service is coming more and more to adopt a policy of feeding. Perhaps someone from the medical service would like to discuss the treatment of bleeding ulcers from this angle.

DR. C. H. WHEELER: The routine which we have employed on the medical service for the last two or possibly three years is to feed all cases of bleeding ulcer from the very beginning. The feedings consist of the routine Sippy regimen with the addition of various types of soft food including milk-toast, custard, junket, smooth cooked cereals, and pureed vegetables. A good many of us who were in the hospital in the days when we used to starve the patients and treat them with parenteral fluid for a period of time, as is done now in the surgery pavilion, feel that since we have been feeding them, the results are better than when nothing was given by mouth. The patients seem to get more prompt relief of pain, the bleeding seems to stop just as quickly, and finally—and this is certainly important—their stay in the hospital and the time required to bring their blood counts back within normal limits appear to be greatly shortened.

One important point which should be emphasized in this connection is that an appreciable percentage of patients with bleeding ulcer are perforating or have perforated when they come into the hospital. Before starting to feed a patient with a bleeding ulcer, one should feel sure that it has not perforated, or is not about to perforate, because if such is the case, naturally one would not think of giving food.

There seems to be evidence accumulating in the literature from both medical and surgical sources that the method of feeding is as good, if not better, than the starvation regimen. That was first pointed out by Meulengracht in Sweden, whose figures Dr. Holman quoted as the best which have been published.

STUDENT: I would like to ask Dr. Wheeler how he determines which cases are about to perforate or penetrate?

DR. WHEELER: Such a case might be one with a history of unusually severe and persistent pain, particularly marked tenderness on abdominal palpation, undue fever or leukocytosis, or the finding of penetration in recent roentgenologic studies of the gastrointestinal tract. In addition, of course, there are the patients who present the findings of frank perforation, such as boardlike rigidity of the abdomen.

DR. ANDRUS: I know of no field in which there is legitimate ground for such radical differences of opinion as in the management of the bleeding ulcer, and I must confess to changing my own opinion from time to time, as I think we are all apt to do, on the basis of spectacular cases.

of the results of the two operations in this manner is not entirely fair to either operative procedure, for there is careful selection of cases that unquestionably affects the end results of both gastro-enterostomy and gastric resection.

Excision of the ulcer and gastro-enterostomy is not widely used in this hospital. The procedure is applicable only in a selected group of cases, and indeed, has been done but 13 times. The results are good in 11 of the 13 cases, but the other 2 have developed new ulcers.

In treating perforated ulcers by simple plication, one can keep the mortality below 10 per cent, but about half of these people will have recurrent ulcer symptoms, and some will require further surgery.

This constitutes a superficial review of our experience in the treatment of the complications of peptic ulcer. Suffice it to say that more detailed analyses are available. From these we have learned that surgery is to be resorted to with caution, but not with stubbornness, and that the choice of procedure in each individual case is most important.

DR. ANDRUS: Dr. Holman will speak about hemorrhage as a complication of ulcer, and I hope will introduce some of his studies on the effects of operation on certain aspects of the physiology of the stomach.

DR. CRANSTON HOLMAN: Opinion as to the best treatment of massive hemorrhage in peptic ulcer varies so greatly that a discussion of the subject seldom fails to end in controversy. The decision as to what type of therapy is indicated should take into consideration several factors: It is well established that most patients with bleeding ulcer recover under any form of conservative therapy and the best recorded results are those of Meulengracht and Hurst, who report a mortality of 1 per cent and 5 per cent, respectively. Unfortunately, other clinics have not had so favorable an experience, and at the New York Hospital where until recently all patients admitted because of massive hemorrhage were treated conservatively, two or three patients died each year as a result of the bleeding. In many of these cases a large eroded artery at the base of the ulcer was found, usually the pancreaticoduodenal artery, and it is unlikely that anything but a direct attack upon this bleeding point could have saved the patient. The mortality in bleeding ulcer is also influenced by age and sex. In our group it was 7 per cent for patients under 40, in contrast to 17 per cent for those over 40. Generally speaking, bleeding ulcer is more hazardous in men than in women.

In considering operative therapy it should be remembered that the operative mortality is relatively high in patients who are bleeding rap-

idly from an ulcer. Finsterer has shown that one way to reduce the high operative mortality is to operate early in the course of the hemorrhage, and he reports a mortality of only 5 per cent when immediate operation is the rule. That figure is undoubtedly too low or too optimistic for all of us to accept as to what might be expected from the general surgeon operating on a large group of patients. However, we may assume that possibly the mortality may be kept down to between 10 or 15 per cent with operation.

In summary, then, we recommend that conservative therapy be used routinely for patients with bleeding ulcer. There is, however, a group of patients who fail to respond to this therapy and will die if it is continued.

In selecting those patients with bleeding ulcer for operation, there are several guides which may be followed with advantage: Operate on the patient who starts bleeding during the course of conservative therapy in the hospital. We had 6 patients who started to bleed under these conditions. Five of them died when the conservative therapy was continued. The sixth patient was operated on and made a satisfactory recovery. Also, operate on the patient who has continuous or repeated bleeding during the first 48 to 72 hours after hospitalization, since in patients with prolonged bleeding the mortality approximates 50 per cent in contrast to 5 per cent for those who respond immediately and satisfactorily to conservative therapy.

When a patient is operated on, a direct attack upon the bleeding point should be made, and the easiest way to do this is to perform a small or moderate sized resection. Neilson has shown the inadequacy of lesser procedures, such as gastrostomy, gastro-enterostomy, and plastic procedures on the duodenum.

In addition, of course, there are the patients who present the findings of frank perforation, such as boardlike rigidity of the abdomen.

DR. ANDRUS: I know of no field in which there is legitimate ground for such radical differences of opinion as in the management of the bleeding ulcer, and I must confess to changing my own opinion from time to time, as I think we are all apt to do, on the basis of spectacular cases.

I personally feel we probably should feed our bleeding ulcer cases more than we do. On the other hand, there are reasons for concluding that, in some cases at least, feeding may not only make the patient worse, but may also tend to hide some complication.

I believe also that more patients with excessive bleeding are admitted to the surgical service than are admitted on medicine. It is a terrifying picture. In an overwhelming proportion of those cases which bleed excessively, the ulcer is on the posterior surface of the duodenum and has eroded into a main branch of the pancreaticoduodenal artery or into the artery itself. At postmortem we see a vessel with an opening which may be 2 or 3 millimeters across and which was plugged temporarily by a clot. I cannot see how anything short of mechanical ligation of that vessel, either with or without resection, can be sure of stopping the hemorrhage. Of course many of these patients come in nearly exsanguinated and are very poor operative risks.

There are many aspects of the surgical treatment of this condition which we could consider, but this question of the handling of bleeding ulcers is so important that perhaps we may confine our discussion for the time being to that.

Will anyone else comment further on this point?

DR. REID R. HEFFNER: Last spring at one of the gastro-enterological meetings, several papers were read on the subject of feeding the bleeding ulcer patient. The consensus of opinion was that it makes no difference whether the patient is fed or not while bleeding, in so far as mortality is concerned, but the authors were unanimous in the opinion that the patients who were fed during the course of their hemorrhage felt better and apparently recovered more quickly.

On the other hand, Dr. T. Grier Miller, of Philadelphia, recently gave some interesting statistics relative to bleeding ulcer. He collected from the literature 5,843 cases treated according to the starvation regimen and morphine, the mortality from which was 8.7 per cent, and in some series it was as high as 25 per cent. In the Scandinavian countries the mortality on the starvation regimen varies from 7 to 10 per cent, and even the most minor hemorrhage as a rule is hospitalized. Now, when Miller examined 1,400 reported cases which were fed during the course of their bleeding the mortality was only 3 per cent. Meulengracht lists his mortality at approximately 2 per cent. Miller cites 31 cases of his own, which were fed, with only one death; at autopsy perforation in addition to hemorrhage was found. He concludes that the mortality is only about 3 per cent when the patient is fed, and, further, raises the question whether it is ever wise to oper-

ate during the course of hemorrhage when the mortality with feeding is so low.

DR. KIRBY A. MARTIN: There are few clinical matters with which we are confronted that present as many variables as the subject under discussion. The questions of when and what to feed a patient who is bleeding from a peptic ulcer have always been considered of the utmost importance.

On this subject two schools of thought have arisen. The older one advises complete fasting, and the more recent one advises small, frequent feedings of a bland diet. Personally, I feel that neither is of prime importance or has much to do with the eventual outcome of the patient with a bleeding ulcer.

When we are faced with this problem in the gastrointestinal clinic, we try to determine the relative value of the patient's feeding habits. If these are suboptimal, as is frequently the case, we feel it advisable to give food supplemented with vitamins. Each case must be judged on its own merits.

With regard to statistical data, the figures for mortality of bleeding ulcer vary in different clinics from 3 per cent to 30 per cent. Let me point out what I believe to be the chief discrepancy in these data. There is nothing to convince one that a bleeding ulcer in Denmark is different from one in South America or the United States, but where these data are gathered, in relation to a community, is the principal difference. First, let us take for example the outpatient department of the New York Hospital. There we see a large number of ulcer patients who bleed, and it will be found that the percentage of active ulcers that bleed is very high indeed, provided one takes the trouble to do frequent stool examinations for occult blood. From this department we send only an occasional patient into the hospital. During the past five years, so far as I know, our mortality rate for the ambulatory patients who bleed has been zero.

Second, on the medical service we find patients who are bleeding, and the clinician feels a little safer by having sent them into the hospital. These patients usually do very well. Third, on the surgical service we find patients who have been transferred from medicine and who have bled severely or long, together with patients who have been admitted from the accident ward where the bleeding is usually dramatic, either as to the speed or the total amount. It is easy to see that the data may vary depending on the entrance to this hospital at which the facts are gathered.

The best arguments, to my knowledge, that have been waged against the Meulengracht figures derive from following this same line of thought. The hospital where Meulengracht worked was State subsidized, making it possible

to hospitalize any patient regardless of the degree of bleeding.

Treatment lies in three directions: preventive, of which we know little; medical, that is, rest, with or without food; and surgical, or ligation of the vessel. The last two are far from ideal. The crux of the problem lies in the size and elasticity of the vessel eroded, and unfortunately the diagnostic means available at present give us little information on this point.

DR. GOLD: Are there no remarks about drugs to control bleeding?

DR. ANDRUS: That is an interesting point. Will anyone comment on that?

DR. HEFFNER: Various styptics by mouth have been tried in bleeding ulcer and discarded. Rarely when the treatment of gastric hemorrhage arises the use of drugs to control bleeding is considered. However, I believe we should mention oxalic acid, since a few reports have occurred recently on its use in cases of this type. In 1939, Steinberg and Brown found that prepared extracts from certain plants accelerated markedly and rapidly the rate of coagulation of the blood; the active substance was identified as oxalic acid. Schuman used a preparation called Koagamin, the oxalic acid content of which is 1 mg. per cc., parenterally in various types of bleeding, including hemorrhage from peptic ulcer, and he reports gratifying results. Jackson, of Madison, Wisconsin, also reported on its use with apparent success in a number of bleeding ulcers. My own experience with Koagamin is limited to one case and, for this reason, I am unable to draw any conclusions regarding the merits of the drug. From reports, it is apparently nontoxic and does shorten the coagulation time of the blood, even in hemophiliacs.

DR. SYDNEY WEINTRAUB: When a patient has recovered from a severe hemorrhage, and then after remaining symptom-free for several years has a recurrence of the hemorrhage, should he be treated medically or should surgical treatment be instituted? Should he be treated differently in the second than in the first episode of bleeding?

DR. ANDRUS: I think Dr. Holman has some figures which bear on that point.

DR. HOLMAN: We found that if a patient has bled once, he is more apt to bleed a second time than a patient who has never bled. We also found that patients who have bled on two occasions are apt to bleed a third time. Keefer and Jordan report that 70 per cent of their patients had a third hemorrhage. Our percentage is about 45 per cent.

Strangely enough, the mortality of these patients does not vary directly with the number of times they bleed, that is, if one considers each single bleeding individually. Of course, the more

times a patient bleeds, the more opportunity he has to die, but for any single episode of bleeding, the person who is bleeding for the fourth time is no more apt to die than the person bleeding for the first time. As a matter of fact, in our series the mortality was a little higher in the patients who bleed for the first time.

DR. WHEELER: What is the difference in mortality in surgical intervention when a patient with bleeding ulcer is admitted with a hemoglobin of 70 per cent and when he comes in with a hemoglobin of 30 per cent? When the medical man calls the surgeon to see the patient with serious bleeding from ulcer, the surgeon may say that this patient has bled so much that he is no longer a risk suitable for operation.

DR. ANDRUS: There is a great difference in operating on a patient with a hemoglobin of 70 per cent and in operating on one with a hemoglobin of 30 per cent. I should say the mortality—and this is a guess—will be at least five or six times as high when the hemoglobin is 30 per cent as when it is 70 per cent. Even when by continuous transfusion it may be possible at least temporarily to boost the hemoglobin, this will still be true.

DR. WHEELER: Does it not automatically follow that a certain percentage of these patients with serious hemorrhage are excluded from the probable benefits of surgery due to the fact that they are seen at a time when operation is no longer feasible because the hemoglobin has fallen to 20 or 30 per cent?

DR. ANDRUS: Let us not say excluded, but the risk is terribly high.

DR. JOHN DEITRICK: It seems to me that it is not the hemoglobin level which is important, but the speed at which the patient bleeds. A patient whose hemoglobin level is low but who is bleeding very slowly is much better off than one who has a high hemoglobin level but who is bleeding very rapidly.

DR. ANDRUS: That is of course true. I was referring to the patient who had been under treatment for a while and during that treatment began to bleed. I did not mean the sudden acute hemorrhage.

DR. DEITRICK: It has been said that if a patient is allowed to bleed for 72 hours his chances of recovery are poor. I believe that during this period he could be maintained in fairly good condition if we followed the patient closely and maintained an adequate hemoglobin level and adequate circulation. In this way, if after two or three days the patient continued to have bloody stools, and operation were ultimately indicated, we could probably reduce the surgical mortality. The clinician cannot wait until so much blood has been lost that severe anoxemia of the tissues

is present. At that point transfusion will not bring about recovery of the circulation, and the patient is a bad operative risk. If he is maintained in good condition by being watched every hour, not once a day, the operative mortality could probably be lowered.

DR. ANDRUS: I am sure that our surgeons are willing to operate on most of the patients you are able to keep in shape, but it is not just a question of keeping them in shape, and it is not just a matter of anoxemia. It is a matter of this hole in the artery. Time after time we see patients transfused either repeatedly with small amounts of blood or slowly with large amounts, in whom you might just as well have poured the blood down the sink so far as raising the hemoglobin is concerned. The opening in the artery is so big that it must be closed, and in the meantime any kind of intravenous therapy simply promotes further bleeding.

DR. DEITRICK: That is true. I recall a young man in whom, in spite of intravenous fluids and transfusions, the condition became so bad that we could not operate, and at autopsy he had a huge, indurated ulcer which had eroded into a large artery.

DR. McKEEN CATTELL: In relation to these statistics, I am not clear as to whether the mortality from surgical operation was influenced by the fact that it was preceded by unsuccessful conservative treatment, and therefore represents a selection of the more severe cases.

DR. ANDRUS: I think we have not gathered a sufficiently large group of cases to be able to answer that question.

DR. CATTELL: Are they at a disadvantage though for having had a period of conservative treatment?

DR. ANDRUS: I do not think we know.

DR. HOLMAN: There are some figures which show quite conclusively that the longer one waits and the longer the patient bleeds, the higher the operative mortality will be.

Finsterer, for instance, divided his patients into two groups: those operated on within forty-eight hours after the onset of bleeding, and those allowed to bleed over a period of days. The mortality for the immediate operation was 5 per cent in comparison with 35 per cent in the group of patients who had bled for some time. Christianson, who collected a large series of cases, also found that the mortality increased as the duration of bleeding increased. That applied to both medically and surgically treated patients. Thus there is considerable evidence to show that continued bleeding bears a direct relation to mortality.

DR. CATTELL: It would appear that the worst cases are automatically selected for surgical treatment.

DR. HOLMAN: Yes, that is usually the case.

DR. CATTELL: In that case we do not have a valid basis for evaluating the relative effectiveness of conservative and surgical treatment.

DR. ANDRUS: It is obvious from this discussion and from any discussion one may read in the literature with regard to bleeding peptic ulcer, that standardization of criteria is essential if statistics are to mean anything. We might well strive in this hospital to establish some criteria by which we can classify the cases on the basis of hemoglobin level, duration of bleeding, previous hemorrhage, age, etc., so that the results obtained by various methods of treatment can be compared. Otherwise, despite the large number of cases collected, no definite conclusions can be drawn.

There are a number of other aspects of the management of the bleeding ulcer. One I should like to mention is the question of x-ray examination in patients who have a fairly brisk hemorrhage.

If surgery is elected in a bleeding case, unless the patient is in extremely poor condition, he should be fluoroscoped before operation in order to locate the ulcer. In this way a mistake in diagnosis could occasionally be avoided, for instance, in the patient who has esophageal varices instead of ulcer. I, myself, have had the embarrassing experience of operating on a patient thought to have an ulcer which had eroded into the pancreaticoduodenal artery, and then of having the patient die 48 hours later from hemorrhage from an ulcer high up on the lesser curvature which I did not see.

Would you care to comment, Dr. Weintraub?

DR. WEINTRAUB: In the past we were very conservative in the handling of bleeding patients and would not submit them to a radiographic examination until about two weeks after the hemorrhage had stopped. Now that we are feeding these patients, there is no objection to the giving of barium which is really soothing to the ulcer. The fluoroscopic examination can be done in the prone and supine positions without manipulation of the abdomen. Such a procedure will not jeopardize the patient.

DR. HEFFNER: On x-ray examination are you not more liable to miss the ulcer when it is bleeding than when it is not bleeding? Is that not your experience?

DR. WEINTRAUB: In about 50 per cent of the ulcer cases with hemorrhage, we cannot find any definite x-ray evidence of the cause of bleeding. Of course in the case of bleeding from an acute ulcer in which there is only superficial erosion, the ulcer cannot be demonstrated by x-ray.

DR. ANDRUS: Another aspect is the importance of environmental factors in these patients.

I am sure that the surgeons, thinking of their postoperative results, appreciate this quite as much as do the internists in the medical treatment of the cases. We know, for example, that in certain types of patients a gastro-enterostomy, which does not lower the acidity as much as do some other types of operation, is much more apt to be followed by marginal ulcer or jejunal ulcer than in other types of patients. Those factors have to be taken into consideration even in deciding upon the type of operation to be performed in a given case.

DR. HARRY GOLD: Have you an idea as to what proportion of the patients with bleeding ulcer leave the hospital without having had a transfusion?

DR. ANDRUS: I know of no statistics on that point.

DR. GOLD: Do you think it is high?

DR. ANDRUS: It is extremely low. This is based partly on the fact brought out by Dr. Martin that only the relatively severe cases of bleeding are hospitalized here.

Summary

DR. JANET TRAVELL: The surgical management of peptic ulcer comprises essentially the treatment of its complications: hemorrhage, penetration, free and subacute perforation, obstruction, and malignant degeneration.

Malignant degeneration of ulcer is probably not common. In making a differential diagnosis between ulcer and cancer it is helpful to remember that a lesion involving the duodenum is almost never malignant, whereas gastric lesions away from the lesser curvature are almost always cancer, especially when located near the pylorus.

The trend in choice of operative procedures at the present time is toward gastric resection. After perforation, however, the simplest procedure, that is, plication of the ulcer, is usually preferable. It has been demonstrated that gastric acidity is not materially influenced by gastric resection providing that only the antrum is removed, whereas, if the resection is extended upward beyond the re-entrant angle on the lesser curvature, postoperative gastric acidity is greatly reduced in the vast majority of cases.

The most controversial aspect of this subject deals with the management of the bleeding ulcer, in particular, as to when surgery is indicated, what the specific indications for surgical interference are, whether a regimen of feeding or starvation should be instituted, and how to interpret the mortality statistics for the results of medical as compared with surgical treatment of this complication. The difficulty in evaluating the results derives chiefly from the lack of standard criteria for the classification of such cases. Both medical and surgical men agree that when the ulcer has eroded into a large artery, usually the pancreaticoduodenal, conservative methods of treatment will fail unless the opening in the artery is closed surgically. The problem lies in knowing when such a situation exists. The clearest indications for surgery seem to be persistence or recurrence of bleeding, or the appearance of bleeding while the patient is in the hospital on a conservative plan of treatment. It is also agreed that a regimen of limited feeding probably does no harm and may prove beneficial in the bleeding ulcer patient. It is noteworthy that drugs are of little avail in the control of such bleeding.

Fluoroscopy should be carried out prior to operation in order, if possible, to locate the bleeding point.

TUBERCULOSIS AND HEALTH ASSOCIATION TO HOLD LUNCHEON

Dr. J. Burns Amberson, Jr., President of the New York Tuberculosis and Health Association, has announced that the Association will hold a luncheon on Wednesday, February 3, 1943, at the Hotel Astor, to which will be invited all those attending the joint Regional Conference on Social Hygiene and the Annual Meeting and Conference on Tuberculosis, being held at the hotel on that day.

Topics to be discussed at the conference on tuberculosis, which is sponsored by the Tuberculosis Sanatorium Conference of Metropolitan New York, include: "Case Finding in Industry"; "Nursing Attendants in the Tuberculosis Hospital"; "The Tuberculosis War Experience in Great Britain"; "The Examination for Tuberculosis of Teachers and School Personnel: Amendment to the New York City Sanitary Code"; and "Registrants Rejected for Tuberculosis by Selective Service." Dr. George Foster Herben, chairman of the Tuberculosis Sanatorium Conference of Metropolitan New York, will preside at the session, which begins at 9:30 A.M.

There will be six separate sessions on "Social Hygiene," with three to be held in the morning from 10:00 A.M. to 12:15 o'clock and three in the afternoon beginning at 3:15 o'clock. "Results of Premarital and Prenatal Examination for Syphilis" will be reported and discussed at one of the morning sessions, while "Public Health Nurses and Social Workers in Relation to National Defense" and "Wartime Venereal Disease Control in the Metropolitan Area—What Official Agencies Are Doing in Social Hygiene" will be the subjects at the others.

"Experimental Methods in the Treatment of Syphilis," "Social Casualties of the War—Current Problems in Delinquency," and "The Adolescent in Wartime" are the topics to be discussed at the afternoon sessions.

INDUSTRIAL HYGIENE

Medical Service Plans Outlined for Larger Industrial Plants of State

ADELAIDE ROSS SMITH, M.D., New York City

(From the New York State Department of Labor, Division of Industrial Hygiene)

EDITOR'S NOTE: This article is the first in a series of three articles on this subject appearing in *The Industrial Bulletin*.

FIRST-AID equipment and service in the small industrial plant have already been discussed in the December, 1941, issue of *The Industrial Bulletin* (page 360). The present article deals with medical service in plants large enough to provide a medical program of broader scope.

In plants large enough to provide more than a simple first-aid kit, all manner of variations in medical services are found, depending upon the number of employees, the type of industry, and the intended scope of the medical program.

According to the American College of Surgeons,¹ an adequate industrial medical service for larger establishments should include the following features:

1. A definitely organized plan for the medical service.

2. A definitely designated staff of qualified physicians and/or surgeons, nurses, and attendants.

3. Adequate emergency, dispensary, and hospital facilities.

4. Pre-employment and periodic physical examinations—to be made only by qualified medical examiners.*

5. Efficient care of all industrial injuries and occupational diseases.

6. First-aid treatment and advice for employees suffering from nonindustrial injuries and illnesses while on duty. For further professional care such employees should be referred to their family physician.

7. Education of the employee in accident prevention and personal hygiene.

8. Elimination or control of all health hazards.

9. Adequate medical records, accessibly filed in the medical department under responsible medical supervision.

10. Supervision of plant sanitation and all health measures for employees by the physician or surgeon in charge.

11. An ethical and cooperative relationship with the family physician.

12. The use of approved hospitals.

Although such a program may seem elaborate and suitable only for very large establishments, an analysis of these functions will show that the basic elements can actually be carried out by a relatively small unit composed, possibly, of only a nurse and a part-time physician, providing that the service is intelligently planned and is executed with interest and attention to detail.

Whether the staff comprises 2 or 20, certain fundamental principles are applicable to all medical "setups." These will be considered under the categories of (1) the medical plant, (2) the medical personnel, and (3) the medical program.

1. The Medical Plant

LOCATION

In considering where to locate the medical department and whether it is to consist of one room or many, the following requirements should be met:

1. *It should have access to good natural light and ventilation.* Not only is natural light necessary for the examining physician, but also it produces a better psychological impression.

2. *There should be freedom from noise and vibration.* Aside from the anomaly of noise and tumult in connection with medical services, the use of the stethoscope is seriously handicapped if surroundings are not quiet.

3. *It should be located in a place of the greatest accessibility to the greatest number.* Many a minor cut has developed a complicating infection because, at the moment of its occurrence, it seemed too much trouble to go all the way to the dispensary.

4. It is also desirable that the medical unit be situated near existing toilet facilities, unless such facilities are to be included in it.

5. Allowance for expansion should also be made, especially if the unit is small. As the

* These should be primarily for placement purposes.

benefits of medical service become evident, it is more than likely that additional space will be needed to permit growth.

APPEARANCE AND ATMOSPHERE

Whatever its size, the quarters occupied by the medical department should be painted in light colors and kept scrupulously clean and shining. Appearance is of great importance in producing within the patient the desired favorable and cooperative psychological reaction to medical care. The physical temperature should be comfortably warm in cold weather and the personal atmosphere one of friendliness and interest.

SIZE AND ARRANGEMENT

The One-Room Dispensary.—The next development in medical facilities after the first-aid kit is the one-room first-aid room, or dispensary, which must need answer all purposes. While such a room is a great improvement over the isolated first-aid kit, it should be realized that it does not offer the most satisfactory working arrangement. If possible, a graduate nurse should be in charge of the dispensary, even if only on a part-time basis. A thin partition or screen is useful in dividing the room into two parts, a waiting room and a treatment room.

Equipment.—This will vary with the size and needs of the particular plant, but it should include at least the items previously listed for the first-aid kit and supplementary material (see *The Industrial Bulletin*, December, 1941) as well as the following:

Basin with running hot and cold water, floor lamp, instrument cabinet, linen and blankets, one or two beds or cots, scales, small sterilizer, telephone, treatment table.

Small office and surgical equipment, such as basins, pitcher, rubber gloves (sterile), scissors, tweezers, forceps, hot-water bottle, ice bag, etc., must also be supplied.

Special equipment may be needed in some plants for special conditions. For example, for the resuscitation of workers exposed to asphyxiant gases, one should have available an inhalator with a tank of 7 per cent carbon dioxide and 93 per cent oxygen.

The Three-Room Dispensary with Rest Rooms.—A more satisfactory arrangement than the one-room dispensary is the three-room unit, consisting of a waiting room, a treatment room, and a room for consultation or for physical examinations, to which, when there are many women employees, a rest room may be added. Other rooms for special purposes may be arranged later to suit the needs and size of the company.

The Waiting Room.—This need not be large if the return visits are distributed throughout the

day so as to prevent congestion. Arrangements should be made for the separation of men and women, and injured workmen should be segregated, so far as possible, from those waiting for physical examinations.

The waiting room should be furnished with suitable seating accommodations for the number expected, with desk and chair for the nurse, and—very important—with filing cabinets for records.

The Examination Room.—The examining room requires comparatively little in the way of equipment and can be quite small. Good daylight is desirable, although this is not absolutely necessary. Its furniture should consist of a desk and chair for the examining physician, a revolving stool, and an examining table.

Aside from this, the only other equipment is that necessary for examinations, much of which may by preference be supplied, or at least chosen, by the physician himself. The following items are suggested: dynamometer, eye chart, finger cots, flesh pencil, head mirror and light, hemoglobinometer, otoscope, percussion hammer, scales,* sphygmomanometer, spot light, stethoscope, thermometer (in sterilizing solution), tongue depressors, tuning fork, Wassermann tubes.

The Treatment Room.—The guiding principle in deciding upon the equipment of the treatment room should be to remember that its purpose is primarily for the treatment of minor injuries. Employees with major injuries should be removed without delay to nearby hospitals. Occasionally, in isolated localities, of course, the industrial establishment must maintain its own hospital, but this situation is exceptional and is not within the scope of the present article.

In general the following recommendations are made for the surgical treatment room:

Size: It should be large enough to treat more than one worker at a time, and when the volume of work is sufficient, each type of injury, such as hand, leg, eye injuries, etc., should have its special place and facilities.

Equipment: It should contain the following furniture: Desk to record all treatments, flat-top examining and operating table for cases requiring the recumbent position, separate eye treatment table with its own solutions and instruments, suitable arm- and leg-rest chairs adjacent to treatment tables equipped with the necessary supplies and instruments.

The following instruments and supplies are recommended by the Council on Industrial Health of the American Medical Association:²

* This item may, if convenient, be placed, in the waiting room where the nurse, to save time, can record height and weight before the physical examination.

INDUSTRIAL HYGIENE

Medical Service Plans Outlined for Larger Industrial Plants of State

ADELAIDE ROSS SMITH, M.D., New York City

(From the New York State Department of Labor, Division of Industrial Hygiene)

EDITOR'S NOTE: This article is the first in a series of three articles on this subject appearing in *The Industrial Bulletin*.

FIRST-AID equipment and service in the small industrial plant have already been discussed in the December, 1941, issue of *The Industrial Bulletin* (page 360). The present article deals with medical service in plants large enough to provide a medical program of broader scope.

In plants large enough to provide more than a simple first-aid kit, all manner of variations in medical services are found, depending upon the number of employees, the type of industry, and the intended scope of the medical program.

According to the American College of Surgeons,¹ an adequate industrial medical service for larger establishments should include the following features:

1. A definitely organized plan for the medical service.

2. A definitely designated staff of qualified physicians and/or surgeons, nurses, and attendants.

3. Adequate emergency, dispensary, and hospital facilities.

4. Pre-employment and periodic physical examinations—to be made only by qualified medical examiners.*

5. Efficient care of all industrial injuries and occupational diseases.

6. First-aid treatment and advice for employees suffering from nonindustrial injuries and illnesses while on duty. For further professional care such employees should be referred to their family physician.

7. Education of the employee in accident prevention and personal hygiene.

8. Elimination or control of all health hazards.

9. Adequate medical records, accessibly filed in the medical department under responsible medical supervision.

10. Supervision of plant sanitation and all health measures for employees by the physician or surgeon in charge.

11. An ethical and cooperative relationship with the family physician.

12. The use of approved hospitals.

Although such a program may seem elaborate and suitable only for very large establishments, an analysis of these functions will show that the basic elements can actually be carried out by a relatively small unit composed, possibly, of only a nurse and a part-time physician, providing that the service is intelligently planned and is executed with interest and attention to detail.

Whether the staff comprises 2 or 20, certain fundamental principles are applicable to all medical "setups." These will be considered under the categories of (1) the medical plant, (2) the medical personnel, and (3) the medical program.

1. The Medical Plant

LOCATION

In considering where to locate the medical department and whether it is to consist of one room or many, the following requirements should be met:

1. *It should have access to good natural light and ventilation.* Not only is natural light necessary for the examining physician, but also it produces a better psychological impression.

2. *There should be freedom from noise and vibration.* Aside from the anomaly of noise and tumult in connection with medical services, the use of the stethoscope is seriously handicapped if surroundings are not quiet.

3. *It should be located in a place of the greatest accessibility to the greatest number.* Many a minor cut has developed a complicating infection because, at the moment of its occurrence, it seemed too much trouble to go all the way to the dispensary.

4. It is also desirable that the medical unit be situated near existing toilet facilities, unless such facilities are to be included in it.

5. Allowance for expansion should also be made, especially if the unit is small. As the

* These should be primarily for placement purposes.

tacts with the plant are limited to emergencies. Under such a plan, he has no opportunity to become sufficiently acquainted with the actual working conditions of the plant, to be able to develop a constructive, preventive health program, or be given responsibility for health maintenance.

THE NURSE

Not less than the doctor, the industrial nurse must be an exceptional individual. She should be, of course, well trained—a woman with executive ability, keen interest in preventive work, and considerable tact; a woman who is not afraid of responsibility, who enjoys association with people, and knows how to get on with them.

There is probably no field of nursing activity which is broader in its demands or more constructive in its activities than that of industrial nursing when the policy of the management is favorable to a far-sighted program. When it is not, the nurse and physician together with patience and persistence should try to convert the management to a broader point of view. This can often be accomplished by a demonstration with a single limited problem.

Qualifications.—The National Organization for Public Health Nursing,³ an authority on standards of nursing education and training, has formulated the following qualifications for the industrial nurse:

I. For the nurse in an industry which provides supervision by a qualified nurse supervisor:

(A) High-school graduation or its educational equivalent is essential. More advanced education on a college level is desirable. Ability to use the typewriter and perform other clerical procedures is helpful to the nurse, especially in smaller industries where clerical assistance is limited.

(B) Fundamental nursing education. The following are essential:

Graduation from a school of nursing accredited by the State Board of Nurse Examiners and connected with a hospital having a daily average of 100 patients, or a minimum of 50 patients with one or more affiliations affording supplementary preparation.

(a) Instruction and experience in the care of men, women, and children, including patients with communicable disease.

(b) Thorough instruction and experience in surgical nursing, including operating room and first aid.

Instruction and experience are desirable in the following: (1) outpatient department, especially in the emergency rooms; (2) psychiatric nursing.

(c) State registration.

II. For the nurse in an industry working without the guidance of a nursing supervisor:

This nurse should be able to plan the nursing program under the general direction of the medical officer and should have a working knowledge of the principles of teaching, social case work, community organization and resources, public health administration, industrial relations, personnel administration, industrial hazards, nutrition, communicable disease, mental hygiene, and personal hygiene, as they affect the individual and his family.

(A) All the preparation listed under I and in addition:

1. At least one year of experience under qualified nursing supervision in a public health nursing service in which practice in the application of technic can be secured.

2. An academic year of study in public health nursing in one of the colleges or universities whose program is approved by the National Organization of Public Health Nurses:

(a) where courses in industrial hygiene and safety are available.

(b) where courses in principles of public health nursing, mental hygiene, social work, preventive medicine, and allied subjects are made applicable to nursing in industry.

(c) where field work includes some experience in industry.

3. Supplementary experience and instruction in operating-room and first-aid nursing, if thorough preparation was not included in the basic nursing education period.

III. For the nurse in a supervisory position: All the preparation under I and II, and in addition:

Successful experience in industrial nursing, part of which is preferably in the type of industrial work in which the nurse is to act as supervisor.

The above, of course, represents the ideal in qualifications. Many nurses in industry unquestionably carry on their work efficiently without extensive additional training, especially when endowed with energy and an interest in preventive medicine. The desirability, however, for the prospective industrial nurse of some special experience in the public health field and some knowledge of the principles of industrial hygiene will be apparent from a consideration of her duties.

Duties.—The following is a list of the duties and activities which should be expected of the industrial nurse:*

* Largely taken from an outline on the subject in *Public Health Nursing* for January, 1942.

Adhesive plaster, assorted bandages, assorted catheters, assorted gauze dressings, assorted hypodermic needles, assorted jars and basins, assorted splints, assorted surgeons' needles, assorted sutures, bandage scissors, cotton, crutches, hand magnifying glass, head mirror, hemostatic forceps, hot-water bottle, ice cap, iris scissors, Loupe, needle holder, safety razor and blades, scalpels, splinter forceps, surgical scissors, syringes, test tubes, tissue forceps, tourniquet.

In the case of both treatment and examination rooms, it is convenient and time-saving to arrange small dressing booths which open into the waiting room on one side and the examination or treatment room on the other. In planning the dispensary, the arrangement of suitable storage space for supplies must not be forgotten.

Additional Facilities in a Large-Scale Medical Unit.—Many additional facilities may be furnished in large industrial plants when the medical department extends its scope beyond physical examination and first-aid treatments. Particularly useful are the following:

A *clinical laboratory* for blood, urine, and serologic examinations is comparatively simple to set up and economical of both time and money, where these tests are included as part of the physical examination.

An *x-ray department* may be very valuable in plants where fractures are not uncommon, or in industries having a silicosis or other dust hazard.

A *physiotherapy department* where injured workmen can receive suitable treatment along these lines can render useful service in shortening the period of disability.

A *department for dental prophylaxis* plays an important part in a preventive health program by forestalling unnecessary disability due to dental conditions.

An *eye department* for complete examination of the eyes, particularly where work may entail special eye strain.

2. Medical Personnel

THE PHYSICIAN

The demands of factory medical service call for certain special qualifications in the physician who is to undertake them, apart from good training and clinical ability. Perhaps the most important of these is what might be described as the "public health point of view." His interest must be in *prevention* fully as much as in *treatment*. He has not only individuals but also, in a true sense, a community under his care and his concern must extend to all circumstances and situations within the community which touch upon its health.

Qualifications for Industrial Work.—The detailed kinds of knowledge, experience, and aptitudes which should be his have been drawn up by the American College of Surgeons¹ as follows:

1. He should be a graduate of an accredited medical school and licensed to practice in the State or province.

2. He should have at least one year's internship in an accredited hospital.

3. He should have some experience in general practice either prior or supplemental to his duties at the plant.

4. He should have a general knowledge of industrial relations, including employment methods and problems, transportation, housing, recreation, educational facilities and methods, and employees' benefit plans.

5. He should be qualified to determine by examination of employees their physical and mental fitness for work.

6. He should have a knowledge of the ingredients and of the toxic or disease-producing properties of all the materials and processes used in the industrial organization which he serves.

7. He should have a knowledge of sanitation, of working conditions, of accident and occupational disease prevention methods, and of preventive health measures in general.

8. He should have a knowledge of the diagnosis and treatment of occupational diseases.

9. He should be competent in the diagnosis and handling of all traumatic lesions which he undertakes to treat.

10. He should be versed in procedure for follow-up and rehabilitation.

11. He should have a knowledge of the workmen's compensation laws.

12. He should have knowledge of an efficient medical record system and of statistical methods.

13. He should have an unbiased viewpoint and a confidence-inspiring personality.

14. He should realize that his first duty should always be to the workmen whom he examines or treats.

15. He should like people.

Time Spent at Plant.—Whether or not the physician spends full time at the plant will depend upon the size and complexity of the medical department. A doctor who spends only part of his time in the plant either by making visits each day or visits at regular times during the week can exercise satisfactory supervision of the medical department providing he has a competent nurse in charge during his absence. This is the most satisfactory setup for the smaller plant.

It is not satisfactory to put the physician on a call basis only, since this means that his con-

THE RISING CURVE OF PEPTIC ULCER IN WAR

"Peptic Ulcer ranks high as a cause of disability for military service. It . . . leads all other digestive diseases as a cause for discharge from the Regular Army."

Kantor, J. L.: Digestive Disease and Military Service, Jnl. A. M. A., Sept. 26, 1942.

THE increased incidence of peptic ulcer among the armed forces, defense workers and civilians today confronts medicine as a major problem.

Of the various types of therapy used to control this problem none has proved itself more valuable than CREAMALIN,

brand of aluminum hydroxide gel.

CREAMALIN, the first aluminum hydroxide gel to be made available to physicians, was also the first to be Council-accepted. CREAMALIN contains approximately 5.5% aluminum hydroxide.

Therapeutic Effects of CREAMALIN

- Pronounced antacid action of 12 times its volume of N/10 HCl in less than 30 minutes (Toepfer's reagent)
- Prolonged action in contrast to fleeting effect of alkalis
- Non-alkaline; non-absorbable; non-toxic
- No acid rebound; no danger of alkalosis
- Prompt and continuous pain relief in uncomplicated cases
- Rapid healing when used with regular ulcer regimen
- Mildly astringent; may reduce digestive action, thus favor clot formation
- Demulcent; gelatinous consistency affords protective coating to ulcer

Modern non-alkaline therapy for peptic ulcer and gastric hyperacidity

ALBA PHARMACEUTICAL COMPANY, INC.,

74 LAIGHT STREET
NEW YORK, N. Y.

1. Management of Dispensary.—This includes responsibility for the running of the medical department and supervision of equipment, supplies, procedures, and records.

2. First Aid.—The industrial nurse should be responsible for first-aid treatment in the dispensary in the absence of the plant physician. At such times she should act on standing orders given by the plant physician. She should also supervise first-aid kits and supplies throughout the plant and may well take on the training of employees in first-aid work.

3. Assistance to Plant Physician.—The amount of aid rendered by the nurse to the plant physician will largely depend upon the wishes of the latter. The nurse will naturally assist the physician with treatments or dressings when necessary. She can facilitate the making of pre-employment and periodic examinations by undertaking, subject to the physician's approval, such duties as history taking, vision and hearing tests, examinations of blood and urine, measurement of blood pressure, and assistance in the making of x-ray examinations.

4. Follow-up of Abnormal Conditions.—Much of the benefit of pre-employment or periodic physical examinations is lost if the correctable physical defects uncovered by such examinations are not corrected as soon as possible. The industrial nurse can play a vital part in the medical program by following up individuals to find out whether defects have received attention by the family physician and if not, striving to bring about correction by persuasion, education, and assistance in referring the individual in question to the proper physician, dentist, or clinic. She is also in a uniquely favorable position to recognize evidence of the effects of any special occupational disease hazards. For example, when a worker in a lead department comes to the plant dispensary for first-aid treatment, a nurse, alert to the possible hazard, may by appropriate questioning discover early evidence of lead poisoning. The same approach pertains to exposure to silica dust, volatile solvents, or other injurious substances.

5. Health and Safety Education.—If she is interested, the plant nurse in her daily contacts with industrial workers can accomplish more toward their education in matters of health and safety than can often be achieved by more formal efforts. She can, moreover, play a valuable part in an educational program by giving talks on health, distributing leaflets, and arranging for movies or other health demonstrations.

6. Supervision of Plant Sanitation.—Supervision of plant sanitation, general cleanliness and good housekeeping, proper maintenance

of toilet and washing facilities, provision of drinking water, etc., falls properly and naturally within the province of the industrial nurse. She should be given the duty of making routine plant inspections and reporting infringements of proper sanitation to the management for correction.

7. Safety Program Participation.—A well-developed safety program includes regular conferences of foremen, safety personnel, and representatives of the plant management to discuss causes and prevention of accidents. The industrial nurse can make a useful contribution to such conferences through her knowledge, gained from intimate personal contact in the medical department, of personal factors which might have played a part in accident causation in any given case.

8. Supervision of Plant Lunch Rooms and Nutrition Program.—The graduate nurse has received instruction in nutrition as part of her training. This knowledge can be put to good use in planning menus and in supervising the industrial plant's nutrition program.

9. Coordination of Medical Department with Other Services.—Within the complicated structure of a large industrial plant the activities of the medical department require coordination with other departments and services, especially the safety department, and the personnel and placing department. Such coordination falls naturally within the sphere of activities of the industrial nurse.

Outside the plant as well, she finds a similar role to play in coordinating the work of her medical department with the various social agencies within the community. In this category would lie such duties as referring employees to outside physicians with a letter describing the need for treatment and cooperation with local agencies to secure rehabilitation of sick or injured employees.

10. Record Keeping.—The keeping of good records is essential to the efficiency of the industrial dispensary and the industrial nurse is the one who must take full responsibility for them. Not only accident records, which are required for compensation purposes, but also medical records should be kept; the latter including all dispensary visits and reasons for absenteeism as well as records of pre-employment and periodic physical examinations.

11. Visiting Nursing Service.—In addition to the duties described above, industrial nurses, in many large plants, participate in a visiting nursing service. Where such a service has been established, it is usually the practice for a plant nurse to visit every employee who has been

Adequate Nutrition

AN IMPORTANT FACTOR IN PREVENTIVE MEDICINE

That optimum nutrition is fully as important as adequate public health measures in the prevention of under-par health and morbidity, is now recognized by all authorities; also, that the promotion of good nutrition demands the satisfaction of all the essential nutritional requirements, and not merely an isolated few.

The balanced composition of New Improved Ovaltine gives this delicious food drink wide applicability in the prevention

and correction of nutritional insufficiency. Rich not only in vitamins but also in virtually all other essential nutrients, Ovaltine complements the average diet to bring the intake of nutritional essentials to the optimum level. No resistance by the patient— young or old—is encountered when Ovaltine is prescribed; its delicious taste assures patient co-operation. Physicians are invited to send for samples. The Wander Co., 360 North Michigan Avenue, Chicago, Illinois.

absent for longer than a given time, usually three days. If this feature is carried out as a true service, and not merely for the purpose of getting information, it will be found helpful in many ways. She can judge whether the physician is needed when he has not been called, or whether his instructions are being properly carried out. When some other disposition of the case is indicated, she can suggest it. If difficult household problems complicate the situation, she can put to use her knowledge of existing social service agencies to help in their solution.

It is possible and often very satisfactory for a plant which is not large enough to maintain its own visiting service to arrange with the

local public health agency for visits to be made to its sick employees. Any scheme of visiting service presupposes that the medical department will be informed daily, from the plant, of absences in the various departments *

SOCIAL HYGIENE DAY

Social Hygiene Day will take its battle stations throughout the country as in former years, despite the gasoline and rubber restrictions which are in force this year. Dr. Walter Clarke, Executive Director of the American Social Hygiene Association, in announcing the annual observance scheduled for Wednesday, February 3, 1943, said that this battle on the home front against venereal disease is nationwide and does not depend upon transportation to rally its fighting forces. Community meetings will take place throughout the land, sponsored by local clubs, church groups, and social and health agencies.

Dr. Clarke pointed out that in wartime more than ever the United States must man its battle stations in every city, town, and hamlet in order to stamp out the venereal diseases at their source. Syphilis and gonorrhea are enemies which threaten us at home. They disable our men at the front, but their roots are on the home front. For this reason Social Hygiene Day this year will assume a greater significance than ever before. It will be observed in every community, no matter how small it may be, by discussion of direct action designed to stamp out the two diseases which are as menacing to our armed forces as the bombs of our enemies.

"During the first world war, there were 157,146 more new cases of syphilis and gonorrhea among United States soldiers, sailors, and marines," Dr. Clarke explained, "than there were wounds in battles. Total absences from duty due to this infection kept the equivalent of 20,600 men out of the fighting for a whole year, men trained for their country's service, men upon whom their country counted for its defense.

"In terms of today's hard-held fronts such a loss would mean the equivalent of the personnel required to man five huge aircraft carriers and nine destroyers.

"No axis enemy could be more destructive than this enemy whom we must defeat on health battle fronts within our own country. We do not need to suffer this loss and do not need gas and tires to meet that enemy and to destroy him. We have the scientific weapons to prevent the spread of the venereal diseases. In wartime the principal function of social hygiene organizations everywhere is to persuade every community to use these weapons effectively. Intelligent cooperation among the health and welfare agencies in every city and town will help stamp out venereal disease and thus help our armed forces to bring us victory on the battle fronts."

REVERSE ENGLISH

Rapidly expanding Washington war agencies can't get enough stenographers, and, as a result, some rather inexperienced girls are getting jobs. We hear that one of these, working for a gold-branded Navy man, was asked to type five copies of a report to be distributed to other important officials at a conference.

She finished the job, then discovered that her carbon paper had been put in wrong—four copies of the report were typed backwards. But, the young lady wasn't stumped. She sent the copies into the conference with a note:

"These can be read easily by using a mirror."

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

General Medicine

ACOURSE of lectures on general medicine has been planned for the Columbia County Medical Society. Lectures will be given at the Hudson City Hospital, Hudson, New York, at 9:15 p.m. The program is as follows:

March 11 "Management of Acute Cardiovascular Emergencies"

Clarence E. de la Chapelle, professor of clinical medicine, New York University College of Medicine.

March 25 "Newer Chemotherapeutic Methods"

Norman Plummer, M.D., assistant professor of clinical medicine, Cornell University Medical College.

April 8 "Benign and Malignant Neoplasms: Diagnosis, Clinical Effects, and Treatment"
J. Maxwell Chamberlain, M.D., principal thoracic surgeon, Homer Folks Tuberculosis Hospital, Oneonta, New York.

April 22 "Pelvic Tumors Complicating Pregnancy, Labor, and the Puerperium"
Harvey B. Matthews, M.D., clinical professor of obstetrics and gynecology, Long Island College of Medicine.

May 6 "The Physical Examination of the Child: Its Importance in Diagnosis"
Marjorie F. Murray, M.D., The Mary Imogene Bassett Hospital, Cooperstown, New York.

Pediatrics

"PREVENTIVE Pediatrics and the Public Health Examination" was the subject of a single lecture arranged for the Cortland County Medical Society on January 15 at 8:30 p.m. at the Cortland County Hospital in Cortland. The speaker was

Dr. A. C. Silverman, professor of clinical pediatrics, Syracuse University College of Medicine.

The lecture was a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of New York.

SCIENTIFIC EXHIBITS

1943

ANNUAL MEETING

Applications for space for the scientific exhibits should be made directly to

Dr. J. G. Fred Hiss,
505 State Tower Building,
Syracuse, New York,

Chairman of Subcommittee on Scientific Exhibits of the Convention Committee.

The Annual Meeting will be held May 3-6, 1943, Hotel Statler, Buffalo, New York.
The list will be closed on February 15, 1943.

PETER IRVING, M.D., Secretary

Fit FOR WAR WORK

THE DEMANDS of war are bringing an increase in the number of middle-aged women in industry. Efficiency demands that they keep fit—physically and emotionally.

It is estimated that 80 per cent of women in this age group experience menopausal symptoms—some severe and well recognized—others milder and more vague. Clinical investigations show that, in a large percentage of cases, adequate estrogenic therapy will eliminate or greatly relieve these symptoms, and thus enable these women to stay "on the job."

The high clinical effectiveness of Amniotin in relieving the distressing vasomotor symptoms of the menopause has been amply demonstrated by numerous clinical reports published during the past 12 years. The product has likewise proved valuable in treating other conditions related to a deficiency of estrogenic substances.

TWO NEW ADVANTAGES . . . The new economy size vials of Amniotin offer two distinct advantages. They provide a substantial saving over the cost of Amniotin in ampuls and they facilitate use of fractional doses without waste of material.

Differing from estrogenic substances containing or derived from a single crystalline factor, Amniotin is a highly purified, non-crystalline preparation of naturally occurring estrogenic substances derived from pregnant mares' urine. Its estrogenic activity is expressed in terms of the equivalent of international units of estrone. In addition to the economy vial packages and the ampuls (both of which are for intramuscular injection) you can secure Amniotin in capsules for oral administration and in pessaries for intravaginal use.

ECONOMY SIZE VIALS

10 cc. . . .	10,000 I.U. per cc.
10 cc. . . .	20,000 I.U. per cc.
20 cc. . . .	2,000 I.U. per cc.

Medical News

Sister Kenny to Teach at N.Y.U.

SISTER Elizabeth Kenny will come to New York this month to teach her technic in a course to be given by New York University on a grant from the National Foundation for Infantile Paralysis.

The University said the course will be the most extensive ever undertaken to prepare technicians to administer the Kenny method. It will mark the first time that Sister Kenny has left the University of Minnesota, where she has taught since 1940, to appear on the teaching staff of another institution.

Physicians and physiotherapists interested in her work have gone to her, although courses without the benefit of her personal instruction have been sponsored recently by the Foundation at universities in other parts of the country.

Sister Kenny will be accompanied by Miss Mary Kenny, her thirty-year-old adopted niece and assistant, who is an expert technician.

Although the program at N.Y.U. will be extensive, starting on February 3, there will be provision for only twenty trainees, who will be selected registered physical therapists. However, plans are also under way for intensive one-week courses for physicians and nurses.

Classes for the course will be held at the New York University College of Medicine, 477 First Avenue, and clinical instruction will be given at the Jersey City Medical Center and at other hospitals in the metropolitan area where there are infantile paralysis patients.

Because of the acute shortage of physical therapy technicians, the classes will be held in the late afternoons and evenings so that those taking the course may continue with their regular work while training.

Dr. George G. Deaver, director of the physical therapy curriculum at the N.Y.U. School of Education, will direct the program, for which regular college credits will be given. Instructors, in addition to Sister Kenny, Miss Kenny, and Dr. Deaver, will include Dr. William Bierman, assistant clinical professor of therapeutics at the N.Y.U. College of Medicine, who will be clinical director; Dr. Joseph Pick, assistant professor of anatomy at the college; Miss Ruth F. Bergmann, chief Kenny technician at the Jersey City Medical Center; and a group of prominent physicians, many of them from the Middle West, including Dr. W. Gudakunst, medical director of the National Foundation for Infantile Paralysis.

Dr. Chace New Head of Academy of Medicine

DR. ARTHUR Freeborn Chace, president of the New York Post-Graduate Medical School and Hospital, assumed the office of president of the New York Academy of Medicine on January 7.

Dr. Chace said in his inaugural address that medicine is "on the threshold of solving many riddles, among which it seems safe to place that great enemy, cancer."

In addition to cancer, other major ills medicine is now about to conquer are "such virus diseases as infantile paralysis, the common cold, and the newer form of virus pneumonia," Dr. Chace added.

Dr. Malcolm Goodridge, the outgoing president of the Academy, said that "as a direct result of the war, medicine will face a vastly changed world and it must take the lead in determining just what its position is to be in the new order or else the initiative will surely pass to those less qualified to act."

"Social and economic trends," Dr. Goodridge predicted, "will affect every phase of life."

According to Dr. Chace, life expectancy at birth has been extended by at least ten years through the work of modern science. The problem thereby created, he declared, "is the treatment of the largely increased illnesses associated with old age."

"The development of the specialty of geriatrics is a pressing problem wherein the Academy must forge ahead in its education program, fitting physicians to meet this demand."

"Our biologic, chemical, and physical discoveries have far outrun our social and economic adjustments, and the war demands have completely thrown society out of gear. In no other branch of science as in medicine have its discoveries been so quickly, and at so little cost, put at the disposal of the public; but still it is not enough. In this lies the Academy's opportunity and obligation to educate the medical profession for their proper use and the laity for proper cooperation."

Outlining the program of the Academy for the near future, Dr. Chace said:

"We propose, to scrutinize carefully the proposals and plans for the postwar world that are formulated by responsible and authoritative agencies. We intend to do this so that we may be fully informed and in a position to contribute effectively to such services as we may be ultimately called on to render."

"We must also devote our attention to those various health problems that issue from food and fuel rationing, from the intensification of our industrial efforts, and from the increased participation of women in war work."

"Civilian defense units must be kept up to date. Catastrophe teams must be kept continually on the alert. Plans must be perfected for the emotional and physical rehabilitation of men returning from the war. The refresher courses in medicine must be given with increasing intensity."

County News

Albany County

Dr. Nicholas P. Teresi has been awarded a fellowship in medicine at the Labey Clinic in Boston.

Dr. Teresi was graduated from Hahnemann Medical College in Philadelphia.

He has been on the medical staffs of the Mt. Morris Sanatorium and the Saratoga County Tuberculosis Hospital. At present, he is on the intern staff of St. Peter's Hospital in Albany. Dr. Teresi

will assume his new duties at the Lahey Clinic on July 1.*

Bronx County

The regular meeting of the county society was held at Burnside Manor on January 20 at 8:00 P.M.

The program opened with an executive session. Three addresses were given in the scientific session: "Prevention and Nonsurgical Treatment of Pulmonary Suppuration," by Harry Wessler, M.D.; "Surgical Aspects of Pulmonary Suppuration," by Harold Neuhoof, M.D.; and "Roentgen Therapy in Prevention and Treatment of Pulmonary Suppuration," by Solomon Ginsburg, M.D.

Another feature was a scientific exhibit—"Acute Mediastinal Infections—Demonstration of X-Ray Films," by Dr. Neuhoof and Dr. Maurice S. Harte; and "Roentgenologic Aspects of Pulmonary Suppuration," in which the following hospitals were represented: Fordham Hospital, by Dr. Henry Hirsch; Lebanon Hospital, by Dr. Jacob Bower; Lincoln Hospital, by Drs. Charles Gottlieb and Harry Weaver; Montefiore Hospital, by Drs. Solomon Fineman, Jacob Bower, and Irving J. Kane; and Morrisania Hospital, by Dr. Samuel F. Weitzner.

Broome County

A standardized county-wide welfare medical plan has been approved for the Broome County Department of Welfare by the State Department of Social Welfare. The county plan started to operate in January, with Dr. F. M. Dyer as medical consultant for the county on a part-time basis.

First public announcement of the program was made by William C. Hawthorne, Broome County welfare commissioner, in his annual report to the Board of Supervisors.

"We have always felt," he wrote, "that the recipients of medical care should have all necessary attention, but it reached the point where we felt that the amount of care authorized should not be determined by anyone outside the medical profession. With the cooperation of the State Department of Social Welfare, Broome County Medical Society, Broome County Dental Society and County Association of Druggists, the superintendents of hospitals, and other professional groups, Broome County has completed a medical plan which is now in full operation."

Mr. Hawthorne explained that the "medical plan represents a standardized agreement of charges for medical care of Broome welfare clients by doctors, dentists, hospitals, and druggists under uniform procedure."

He explained that the county will operate the plan on a zone basis for medical calls and that the program contemplates no change in over-all medical costs from those of former years. Medical care during the fiscal year which ended October 31, 1942, cost \$55,100.96 for treatment of welfare cases in area hospitals and professional services in hospitals.

The plan is in line with similar plans either already operating or proposed for upstate counties under state department jurisdiction.*

Cayuga County

Dr. Frank L. DeFurio, Auburn physician, has been appointed coroner of Cayuga County to succeed the late Dr. Raymond C. Almy. The appointment was made by Governor Charles Poletti.

Dr. DeFurio will hold office as coroner until December 31, 1943, the incumbent to take over after that date to be decided at the 1943 fall elections.

The duties of the coroner will not be new to Dr. DeFurio, as he served from August, 1937, to January 1, 1938, as successor to the late Dr. A. F. Hogman.*

Jefferson County

Dr. Leandro M. Tocantine, associate professor of medicine at Jefferson Medical College, Philadelphia, was the speaker at the January meeting of the Medical Society of Schenectady County held December 29 at 9 o'clock in the auditorium of the Whitmore Home of Ellis Hospital.

Dr. Tocantine, who is also director of hematology of Jefferson Medical College Hospital, Philadelphia, spoke on "Nutritional and Metabolic Aspects of Disorders of the Blood."*

Kings County

The county society has approved a plan to conduct physical examinations for teen-age high-school students who expect to be called for war service.

The Board of Education has asked that all such youths go to family physicians for an examination. In the event that some have no family physician and cannot pay the usual fee, volunteer physicians will be asked to make the examinations at their offices.

A roster of physicians who have offered to participate in the plan is being prepared by the director of medical activities of the medical society.

Each high school will be given a copy of the roster through the office of the Department of Health Education of the Board of Education. Each student will have an opportunity to select from the roster a physician of his choice.

Each high school will assume the responsibility for the follow-up care of defects discovered in the examinations, either through the aid of the boy's own physician wherever possible, or through co-operation with municipal clinics.

The plan is only for the pre-induction group of high-school students 16 years old and older, for the duration.

Dr. Charles F. McCarty, director of medical activities of the medical society, is receiving registrations of men and women physicians at the headquarters of the society, 1313 Bedford Avenue.*

The regular annual meeting of the Pan-American Medical Association, Brooklyn and Long Island Chapter, was held December 4 at the home of the president, 18 Prospect Park West, Brooklyn.

The following officers were elected: president, Edwin A. Griffin, M.D.; vice-presidents, F. Raymond Surber, M.D., A. W. Martin Marino, M.D., and Milton B. Bergmann, M.D.; secretary, Frank E. Mallon, M.D.; treasurer, Morris W. Henry, M.D.

It was decided to have a symposium on "Sudden Death in Surgical Cases," at a Brooklyn hospital during February.

During the regular monthly meeting of the Brooklyn Urological Society the following officers were elected for 1943:

President, Dr. John J. Bottone; vice-president, Dr. Oscar Schoenemann; secretary-treasurer, Dr. Francis O. Osterhus.

Patients with Long-Standing Ptosis

A

B

A: Patient with extreme case of entropion. Probably has movable kidney, also.

B: Same patient in the Spencer that was designed especially for her. Note support given—and improvement in posture.

**Are Grateful
For Relief
Given By
Individually
Designed
SPENCER
SUPPORT**

Doctors have remarked the immediate favorable reaction of patients with long-standing ptosis to a Spencer Support. This is because the Spencer has been designed especially for patient to improve posture.

A Spencer Support gently lifts sagging organs, while allowing freedom at upper abdomen. This, plus posture improvement, aids digestion, elimination and improves circulation of blood through abdomen. Appetite usually improves.

Every Spencer is individually designed for patient, of non-elastic material. Hence, the support it provides is constant, and the Spencer can be—and IS—guaranteed NEVER to lose its shape. Why prescribe a support that soon loses its shape and becomes useless before worn out? Spencers are light, flexible, durable, easily laundered.

For service look in telephone book under "Spencer Corsetiere" or write direct to us.

Address.....C-2

[Continued from page 272]

Dr. M. Ruiz Castaneda, official of the Department of Public Health of Mexico, who is visiting in the United States as a guest of the Department of State, spoke on typhus fever at a meeting of the Research Society of the Long Island College of Medicine on January 2.

The entire student body had been invited to hear Dr. Castaneda's lecture. This subject, according to the announcement issued by the college, is of paramount importance in the teaching of military medicine and is one of the phases of tropical medicine being stressed there at the present time.

According to Dr. Wade W. Oliver, professor of bacteriology and head of the Department of Bacteriology of the college, it is of particular value to medical students of the college at this time to have heard Dr. Castaneda speak on his researches, since typhus fever is a disease which is world-wide in distribution and has raged in violent epidemic proportions in the wake of every war fought in Europe during modern times.*

The county society and the Academy of Medicine of Brooklyn held a stated meeting on Tuesday, January 19, at 8:45 p.m. in MacNaughton Auditorium.

The scientific program included "The Role of the County Society in the War" (Inaugural Address), by John J. Gainey, M.D., F.A.C.S., president of the Medical Society of the County of Kings and of the Academy of Medicine of Brooklyn; and "The Use of Malaria in the Treatment of Syphilis," by Arthur W. Grace, M.D., F.A.C.P., professor of dermatology and syphilology, Long Island College of Medicine.

Livingston County

Child health consultations are sponsored by the Livingston County Medical Society throughout the county for the purpose of giving every child between the ages of 6 months and 6 years an opportunity to have a thorough physical examination at least once a year. Children in this age group who are not already being examined by their family physician once a year are invited to attend the consultation.

At the consultation the children are examined by a local physician and have their teeth cleaned by a dental hygienist, and they have the privilege of receiving dental care at a dental clinic.

The aim of the annual physical examination is to encourage parents to have correction made of such conditions as defective tonsils, teeth, hernia, malnutrition, etc., so that the children will be ready to enter school in good health.

From time to time these consultations are held in Caledonia. Parents wishing to take advantage of them may leave their names with Mrs. Harold King, after which an appointment will be given them.*

Madison County

A recent report stressed the part that public health nurses are playing in relieving the serious shortage of physicians and nurses and the overcrowded condition of hospitals in the county. The following paragraph, which gives some interesting figures on this subject, was clipped from the *Hamilton Republican* of December 31:

"Figures indicated that the nurses covered 52,535 miles and spent 10,389 hours on duty during the

year, making some 6,393 visits. Most of these visits were maternity calls, before, during, and after delivery. Children received 1,500 visits for purposes of health supervision; 936 visits were made to give nursing care during other illness; and there were 692 visits to cases and contacts of tuberculosis. At least 3,000 school children in forty-six schools of the county are under the direct supervision of the county nurses."

Nassau County

The effect of the war on doctors of Nassau County and the work doctors are doing on selective service boards were outlined by Dr. Smith A. Combes, former village health officer and now examining officer for the local draft board, at a meeting of the Hempstead Lions Club on December 23.

One hundred and fifty members of the Nassau County Medical Society, comprising about 30 per cent of the total membership, are now in the armed forces, Dr. Combes told the Lions. Most of the doctors in service are under 37 years of age and were formerly the most active general practitioners.*

New York County

Students will be admitted in February for occupational and physical therapy courses at Columbia University in an effort to relieve the shortage of technicians in this field in the Army and Navy. Professor Harry Morgan Ayres, acting director of University Extension, has announced.

The course in physical therapy, instituted last September, calls for two years of work, and the course in occupational therapy three years. While brief emergency courses have been established elsewhere, Columbia is giving the full course, it was explained, not only to train students for immediate war duties but also to meet "the increasing demands that will be made in the postwar rehabilitation period."*

On January 12 New York newspapers carried an exciting story of a surgical feat by a New Yorker. We quote the following account from the *Herald Tribune*:

"Lieutenant William W. Walker (j.g.), of the medical corps of the United States Naval Reserve, successfully performed an emergency appendectomy last week aboard a destroyer in a sea so rough that he was lashed to stanchions to help him keep a steady hand . . . The patient was another lieutenant, who on a previous trip saved Dr. Walker from possible serious injury or death.

"During the same week Lieutenant Walker, who is twenty-eight years old, performed a second appendectomy, froze a third appendix to postpone an operation, and set a fractured arm, according to his commander, Lieutenant-Commander George C. Seay.

"Lieutenant Walker, the son of Dr. William J. Walker, a New York police surgeon, of 840 Morris Park Avenue, the Bronx, [modestly] attributes the success with which he managed the series of medical emergencies to the cooperation of Commander Seay, to a pharmacist's mate who assisted him, and to a sympathetic crew."

Dr. John H. Barrett, of Palestine, Texas, who for the past two years has been a resident surgeon in

[Continued on page 276]

WHO ARE THE MEN BEHIND THE "FACTS"

?

FACTS quoted by PHILIP MORRIS are based on studies conducted by recognized authorities whose work is known to the profession...whose findings have been published in leading medical journals.*

Their tests, not only in the laboratory, but in the clinic as well, have conclusively *proved* PHILIP MORRIS Cigarettes to be *definitely and measurably less irritating* to the sensitive tissues of the nose and throat . . . an advantage due to a difference in the manufacture of PHILIP MORRIS.

May we suggest that you try PHILIP MORRIS, and observe the results for yourself?

[Continued from page 274]

otolaryngology at the Manhattan Eye, Ear, and Throat Hospital, has returned to Texas to become associated with Drs. Foster, Logue, Cody, and Robison of the Houston Eye, Ear, and Throat Hospital.

Dr. Bret Ratner, clinical professor of pediatrics, New York University College of Medicine, has been appointed visiting pediatrician and director of pediatrics at the Sea View Hospital, New York City, to succeed Dr. Bela Schick, who has retired and is now consultant pediatrician.

Dr. George B. Dorff, Brooklyn endocrinologist and specialist in glandular disturbances, was inducted as president of the East New York Medical Society at its thirty-third annual installation meeting in the Temple Auditorium on January 3. He succeeds Dr. Morris Ant.

Dr. Dorff is in charge of the Children's Endocrine Clinic at Bellevue Hospital, Manhattan, and at Beth-El Hospital, Brooklyn. He is a Fellow of the American College of Physicians.

Other officers inducted, in addition to Dr. Dorff, by Dr. William Levine, a former president of the society who acted as the installing officer, were: Dr. Max Dannenberg and Dr. Jacob S. Reilly, vice-presidents; Dr. Harry Bloch, treasurer; Dr. Gerry L. Esersky, assistant treasurer; Dr. Mortimer M. Kopp, corresponding secretary; Dr. Harold Levy, recording secretary; Dr. Harry Rascoff, historian; Dr. A. M. Litvak, program chairman.

Dr. Raphael Kurzkrook spoke on "Sterility" and Dr. A. Weissman on "A New Pregnancy Test."

Officials of the Kings County Medical Society were guests at the meeting, including Dr. John Gainey, president; Dr. Leo Schwartz, president-elect; Dr. Charles McCarty, medical director; Dr. B. M. Bernstein, secretary; and Dr. A. Koplowitz of the economics committee.

Approximately one-fourth of the East New York Medical Society's membership of over 400 is now in the service and the remainder, in addition to heavily increased medical duties, is actively engaged in civilian defense endeavors.*

Friends and colleagues of Dr. A. Bern Hirsh paid tribute to him at a dinner held before his retirement as managing editor of the *Journal of the Medical Society of the County of New York* on December 31.

"Metropolitan News Briefs," a regular feature in the *New York County Journal*, carried these items in its January 9 issue:

"New Yorkers who will participate in the Fifth Annual Forum on Allergy to be held in Cleveland, January 9-10, are Dr. Mary E. H. Loveless, on 'The Immunology of the Atopic Reactions,' and Dr. Bret Ratner, on 'The Management of Asthma in Children.'"

"Ernest F. Krug, M.D., has been appointed consulting ophthalmologist at Lenox Hill Hospital."

"At the annual meeting of the Medical Alliance, Inc., held on December 24, the following officers were elected for 1943: Jacob A. Scal, president; Julius Ferber, secretary; Ellis M. Schwartz, treasurer; Barnett Dobrow, Solomon Feigin, and

Morris Schoenfeld, board of governors for three years."

"William T. Carstarphen, M.D., is serving as chief medical officer of the Rohwer War Relocation Project, in Washington, D.C."

"The following New York City physicians will participate in the fifth Annual Congress on Industrial Health, sponsored by the Council on Industrial Health of the American Medical Association, which will meet in Chicago January 11-13: Roy S. Bonsib, on 'Ocular Signs of Industrial Poisoning'; Leverett D. Bristol, on 'Problems of Organization and Administration' (in the immunization of industrial workers); M. H. Manson, on 'How to Make Industrial Medical Records Work for You'; and Henry D. Sayer, on 'Workmen's Compensation: The Shape of Things to Come.'"

Niagara County

Dr. Lemuel R. Hurlbut, of Lockport, has been appointed by the Board of Education as medical inspector of the Lockport public schools to fill a vacancy left by the death of Dr. Henry H. Mayne.

Dr. Hurlbut has been a practicing physician in Niagara County since 1906. During World War I he served in the Medical Corps of the U.S. Army, being discharged in 1919 with the rank of major. He was elected a Niagara County coroner at the general election last November and assumed that office on January 1.

Ontario County

The first regular quarterly meeting of the county society for 1943 was held in Canandaigua at the Canandaigua Hotel on January 12. A business meeting and dinner preceded the scientific session, which featured a full color movie, with sound, entitled "Peptic Ulcer." Discussion of the movie was given by Dr. W. J. M. Scott, associate professor of surgery, University of Rochester School of Medicine; Dr. A. S. Taylor, chief surgeon and superintendent of Clifton Springs Sanitarium and Clinic; and Dr. S. A. Munford, chief of medical staff of Clifton Springs Sanitarium and Clinic.

Otsego County

As a contribution to the war effort, the library of the Mary Imogene Bassett Hospital at Cooperstown has collected books, pamphlets, reprints, and government publications on the various aspects of war medicine and surgery, and is equipped with a new Spencer Microfilm Reader, thus making available to members of the medical profession within the neighboring communities all the latest material in these fields.

A full-time librarian is on duty and ready to offer assistance in assembling material for special studies. The facilities of the library are available not only to the staff members, but also to any members of the medical profession in the vicinity and neighboring counties who care to make use of them. Inquiries should be addressed to Miss Mary E. Davenport, librarian.

Schenectady County

Dr. Leandro M. Tocantine, associate professor of medicine at Jefferson Medical College and director of hematology at the Jefferson Medical College Hospital, spoke on nutritional and metabolic aspects of disorders of the blood at the Schenectady County Medical Society meeting on December 29 in the Nurses' Home Auditorium, Ellis Hospital.*

Some overworked doctor may appreciate knowing that . . .

Biolac saves time

Biolac provides for all nutritional needs of the young infant except vitamin C. You save valuable time because there are no extra formula ingredients to be calculated.

Biolac assures formula safety

Since mothers simply dilute Biolac with boiled water as you prescribe, there is less chance of upsets arising from errors or contamination in preparing formulas.

NO LACK IN BIOLAC

Borden's complete infant formula

● Biolac is prepared from whole milk, skim milk, lactose, Vitamin B₁, concentrate of Vitamins A and D from cod liver oil, and ferric citrate. It is evapo-

rated, homogenized, and sterilized. For professional information, write Borden's Prescription Products Division, 350 Madison Avenue, New York City.

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

[Continued from page 276]

Suffolk County

Recently many localities throughout New York State have reported alarming increases in juvenile delinquency—in some instances as high as 50 per cent. It is, therefore, with justifiable pride that Suffolk County can report a *drop* of almost 50 per cent in delinquency referrals for the fiscal year ending October 31, 1942, over a similar period in 1941.—*News Letter, Suffolk Co. Med. Soc.*

The quarterly meeting of the county society was held on January 27 at Friede's Riverside Inn in Smithtown.

For the purpose of providing financial assistance to the families of members of the staff who enter the armed forces, the members of the medical staff of Huntington Hospital have instituted a fund to which its members contribute. From this fund the families receive each month \$100 with which to maintain the expenses of home, insurance, and education of children, that might otherwise be impossible on the comparatively lower income of an officer. This plan is unique in the State of New York but is being studied by the Suffolk County Medical Society for possible adoption throughout Suffolk County.*

Westchester County

"Society Aims in 1943" were published in the January issue of the *Westchester Bulletin*. These aims are:

"1. To maintain the opportunities of practicing physicians to keep abreast of advances in medicine through as complete a schedule of society meetings as may be possible under the circumstances.

"2. To maintain communications with our members in service and to safeguard, in so far as possible,

their professional good-will while they are absent in the service of our country.

"3. To satisfy as rapidly and as adequately as may be possible the requirements of the 'home front' for medical service in the event of emergency or epidemic, and despite diminished numbers of medical personnel available.

"4. To seek out every promising opportunity for the extension of preventive medicine and health service to the public, with particular attention to industrial workers.

"5. To promote the acceptance of medical expense insurance and to assure its successful and satisfactory operation by every means at our command."

The county society had as its guest speaker at its regular meeting on January 19 Dr. Cornelius P. Rhoads, director of the Memorial Hospital in New York City. His topic was "Nutrition and Cancer."

Dr. Rhoads was formerly pathologist at the Hospital of the Rockefeller Institute for Medical Research. He did some important work on sprue and related anemias during the past few years, both in Puerto Rico and in New York. He is perhaps most widely known for his more recent work in the investigation of the influence of nutritional factors on the growth of tumors, and, conversely, the influence of tumors on the nutritional status of patients.

Dr. Rhoads is also a member of the Committee on Blood Substitutes of the National Research Council and played an important part in developing the present technic of the American Red Cross in blood procurement.

Dr. Samuel W. Hamilton, formerly of the staff of the New York Hospital, Westchester Division, is coauthor, with Edith M. Stern, of a new book, *Mental Illness—A Guide for the Family*.

Woman's Auxiliary

To the Medical Society of the State of New York

ATTENTION! County Chairmen on Press and Publicity:

More news will be welcomed by your state chairman. Be sure to send it in before the first and fifteenth of the month. It is through your cooperation that we know what each county auxiliary is doing. We have all had a happy holiday

season. Let's continue our good work through 1943.

The February board meeting will be held at the DeWitt Clinton Hotel in Albany on February 14 and 15. Please make your reservation early. You will hear more about this meeting. This is just an advance notice.

County News

Fulton. Mrs. M. F. Drury entertained the members of the woman's auxiliary at her home in Gloversville. Twenty-four members were present.

At the business session it was reported that the members had filled fifteen embarkation bags which have been sent to soldiers. Each member has also contributed a book for service men. A Christmas party was held after the business session, with Mrs. B. G. McKillip in charge of the program. Mrs. Clara Spencer sang a solo, and Miss Ruth Test gave a reading. Mr. Richard T. Furlong, acting as Santa Claus, distributed gifts. Refreshments were served under the direction of a committee headed by Mrs. Fred Lenz.

Nassau. The Nassau Hospital auditorium in Mineola was decorated in the Christmas theme for the annual Christmas party. A large Christmas tree was set in the center of the room and gifts placed around it—not for adults, but for the children, under the Nassau County Foster Parents program.

Mrs. Arthur D. Jacques presided at a short business meeting, when Mrs. J. C. Selicetti was received as a new member. Mrs. Jacques named the following as a budget committee: Mrs. Louis A. VanKleeck, Mrs. Albert M. Bell, Mrs. Arthur Chalmers Martin, and Mrs. Howard F. Munro. Military bridge was played, prizes going to Mrs. Nathaniel Robin, Mrs. William G. Burke, Mrs. Francis J. Buckley, Mrs. Walter F. Stillger, and Mrs. Joseph W. Wycoff. Mrs. S. Alton Dallgaard accompanied the singing of carols; and tea was served from a table decorated by Mrs. Martin. Mrs. Vincent C. Webb is chairman of hospitality.

In troubled times such as these that we are passing through, there is hardly a home in which one or more of the loved ones are not in the service of their country. These lines, spoken by Stephen Decatur, come to me, and I feel that they will give all of us a great deal of courage to carry on:

"Our Country—may she ever be right!

Or wrong
Our Country."

LECTURES ON PSYCHOTHERAPY OF THE CHILD

The Association for the Advancement of Psychotherapy began in January a series of discussion forums on recent advancements in the psychotherapy of the child, arranged by Dr. Ernest Harms, editor of *The Nervous Child*. Programs for the remaining sessions are as follows:

Third Session: February 10. "Adolescents in Need of Psychotherapy." Speakers: E. DeAlton Partridge, Ph.D., New Jersey Teachers' College, author of *The Social Psychology of Adolescence*; Theodore Abel, Ph.D., Letchworth Village, author of *The Subnormal Adolescent Girl*.

Fourth Session: February 24. "Mental Hygiene in School and Psychotherapy." Speakers: Lester Crow, Ph.D., Brooklyn College, and Alice Crow, Ph.D., Dean, Girls' High School, Brooklyn, authors of *Mental Hygiene in School and Home Life*.

Fifth Session: March 10. "The Nutritional Basis of Mental Disorders in Children." Chairman: J. Newton Kugelmass, M.D., Ph.D., Sc.D., author

of *Superior Children Through Modern Nutrition*.
Sixth Session: March 24. "Clinical Psychotherapy of the Child." Speakers: Bernard L. Paccella, M.D., New York State Psychiatric Institute; Lewis R. Wohlberg, M.D., Kings Park State Hospital.

Seventh Session: April 14. "Preschool Education and Psychotherapy." Speakers: Mary S. Fisher, Ph.D., Vassar College; Cornelia Goldsmith, Ph.D., Vassar College; Benjamin Spock, M.D.; Margaret Wagner, Dean, Ann Reno Institute; Dr. Barbara Birber and Louise P. Woodcock, Bank Street Schools.

Eighth Session: April 28. "The Role of the Family in the Psychotherapy of the Child." Chairman: Leo Kanner, M.D., Johns Hopkins University, Baltimore, Maryland.

Ninth Session: May 5. "Adult Psychotherapy and Child Psychotherapy." Chairman: Frederic J. Farnell, M.D., New York Medical College.

TRAVEL MEDICINE

No Refunds

Travel Items, a war baby of the travel industry, just published the newest news on railroad reservations and cancellations—

According to the bulletin, "Railroads are experiencing peak loads of passengers these days, and with accommodations growing increasingly scarce there are certain peacetime privileges that the traveler can no longer enjoy. One of these vanished prerogatives is that of blandly ignoring a Pullman reservation and receiving a refund.

"At insistence of government agencies the Pullman company has sharply curtailed the practice of refunds. The procedure boils down to this: To be sure of getting his money back on a reservation he is not able to use, the traveler must notify the railroad or any ticket office (not necessarily the one at which he bought the space) before train time. About the only acceptable excuse for not doing so is when a connecting train fails to arrive on time."

And here's how to obey the rule:

"The best way to make a cancellation is to take the ticket to the station, but if this is impossible a telephone call will suffice, provided the caller has at hand all the data on the ticket.

"If the ticket-holder cancels after the train has left, it is sometimes possible to wire ahead to the

Pullman conductor and authorize him to sell the space for the remainder of the trip. When this is done the original reserver gets a proportional refund.

"All this is a sharp departure from the policy that has been followed since the last war. But with all the improvements in the 7,000 Pullman cars now operating, none has ever been built with elastic sides, so capacity means *capacity*—period "

But the soldier's share:

"On certain days more than half of those 7,000 Pullmans will be in use transporting troops. In fact during 1942 men in the armed forces made more than 8,000,000 trips by Pullman. (These figures do not include service men on furloughs who were lucky enough to find accommodations.)

"Added to this is the great bulk of travel brought about by the war industries, plus the usual civilian transportation—all competing for the same limited facilities.

"So even if you can afford to pay for Pullman accommodations that you don't use you should make any necessary cancellations promptly because:

"1. If you don't need the space, someone else does.

"2. If you don't need the money, Uncle Sam does "

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N.Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and interest to our readers.

REVIEWED

Collected Papers of the Mayo Clinic and the Mayo Foundation. Edited by Richard M. Hewitt, M.D., et al. Volume XXXIII, 1941. Octavo of 1,099 pages, illustrated. Philadelphia, W. B. Saunders Company, 1942. Cloth. \$11.50.

The *Collected Papers of the Mayo Clinic and Mayo Foundation* for 1941, as usual, cover a wide range of subjects. The authors, thoroughly versed in their respective fields, give us the benefit of their personal experiences and bring our knowledge up to the minute. These personal opinions, based on numerous observations, are especially important in evaluating new remedies and new methods of procedure.

There are eleven papers dealing with aviation medicine. As in the past, the largest number of papers deal with the alimentary tract—benign lesions of the lower esophagus, early recognition of gastric carcinoma, portal cirrhosis, pancreatic lithiasis, regional enteritis, carcinoids, and the finding of asymptomatic perirectal abscess as the cause of obscure fever.

Among the papers on the genitourinary tract the discussion of prognosis, bilateral renal tuberculosis, the restricted value of removal of surgical kidney lesions for the cure of hypertension, the production of hypertension by perinephritis, and the recognition of rupture of graafian follicle and corpus luteum cysts as the cause of acute abdominal pain will reward all readers for their pronounced value.

The discussions of the treatment of hyperthyroidism, when complicated by diabetes, the recognition of the malignant pathology of so-called lateral aberrant thyroid tumors, the independence of hypertension in hyperthyroidism, the Cutler-Power-Wilder salt restriction test in diabetes, and the recognition and differential diagnosis of spontaneous hypoglycemic states are excellent.

Many valuable pointers for the clinician and surgeon will be found among the papers dealing with the diseases of the blood, circulatory organs, skin, syphilis, head, trunk, extremities, central nervous system, radiology, physical medicine, and anesthesia.

The book must be read from cover to cover to be thoroughly appreciated. As in the years gone by, it serves as the annual refresher course in medicine and surgery. Excellent illustrations and charts enhance the value of the text.

MEYER A. RABINOWITZ

I. **Help Your Doctor to Help You When You Have High Blood Pressure.** Duodecimo of 25 pages. New York, Harper & Brothers, 1942. Cloth, \$0.95.

II. **Help Your Doctor to Help You When You Have Insomnia.** Duodecimo of 29 pages. Cloth, \$0.95.

III. **Help Your Doctor to Help You When You Have Heart Disease.** Duodecimo of 47 pages. Cloth, \$0.95.

IV. **Help Your Doctor to Help You When You Have Constipation.** Duodecimo of 59 pages. Cloth, \$0.95.

I. This discussion takes up the modern concepts in the etiology and treatment of high blood

pressure. It debunks some of the older ideas and warns against overoptimism as to results to be obtained by various medical and surgical procedures.

II. The individual and personal symptom, insomnia, scarcely requires a book for its presentation. However, the subject is intelligently set forth for the lay reader. Again drugs are mentioned even though they cannot ordinarily be obtained without a doctor's prescription.

III. This is an excellent little book on the problems of heart disease. The subject is well presented. It discusses every phase of heart disease intelligently and simply. Any intelligent layman should be able to understand it with ease.

IV. The difficult subject of constipation is handled in this little volume by giving the varying points of view in its management. Diet, exercise, and habit are stressed as they should be. Note is made of the fact that treatment of this common condition is individual and does not always respond as one expects. Criticism must be made of the enumeration of cathartics on the market, both proprietary and U.S.P., with the dosage and method of use. One must repeat that these books for the layman must shun any semblance of suggestions at self-medication.

In general, one might add that these little books do fulfill their purpose in presenting to the lay reader modern views on common conditions.

BENJAMIN M. BERNSTEIN

Diabetes Mellitus. By Zoltan T. Wirtschafter, M.D., and Morton Korenberg, M.D. Octavo of 186 pages. Baltimore, Williams & Wilkins Company, 1942. Cloth, \$2.50.

This small volume is one of the most satisfactory on the subject of diabetes. The presentation is such that it must be considered a modified "source book," since excerpts, abstracts, and an excellent reference bibliography of 336 items are summarized and quoted throughout the text. The reviewer has never seen so much information compressed so lucidly within so small a compass.

History, glycogenesis, glycogenolysis, ketosis, acidosis, glucose tolerance tests, and vitamin and endocrine consideration precede a description of the visceral lesions of diabetes. There is an interesting chapter comprising discussions of xanthomatosis, lipid dystrophy, transverse nail furrowing, cataract, retinitis, coronary sclerosis, achlorhydria, Kimmelstiel-Wilson intercapillary nephritis, and neuritis.

The book then moves into the symptomatology and treatment of the disease and ends with a chapter on diabetic coma. Appropriately the last quotation is from Claude Bernard concerning the "liquid milieu interieur." The reviewer's enthusiasm for the book is undiluted.

FRANK BETHEL CROSS

The Mind and Its Disorders. By James N. Brawner, M.D. Octavo of 228 pages, illustrated. Atlanta, Ga., Walter W. Brown Publishing Company, 1942. Cloth, \$3.50.

[Continued on page 284]

clinical value. This value, it would seem, has been greatly advanced by excellent editing and arrangement together with an unusual degree of easy and enjoyable readability. This book is referred to in the foreword by Dr. Donald C. Balfour as a valuable monograph on the subject of cancer of the stomach. It has fully justified its appearance in the form of a valuable book.

JOSEPH RAPHAEL

Hospital Discharge Study. An analysis of 576,623 patients discharged from hospitals in New York City in 1933. By Neva R. Deardorff, Ph.D., and Marta Fraenkel, M.D. Volume One—Hospitals and Hospital Patients in New York City. Octavo of 209 pages. New York, Welfare Council, 1942. Cloth, \$1.00.

Reading through this book, one realizes the vast amount of work entailed in compiling the figures. If the survey is to be complete, it should include all hospital discharges, whether private or ward. A definite criterion regarding the results is also clearly indicated. Without such, the statistics are of little value. For instance, one hospital may discharge a patient as "improved" after the incision of a localized abscess or the splinting of a greenstick fracture, while another marks "recovered" when a patient has been operated on for cancer of the stomach. End results, therefore, should not be coded without the benefit of a careful follow-up.

The discharge diagnosis will probably be much more accurate as most of the approved hospitals are using the *Standard Nomenclature of Disease*.

Incidentally, if another survey is to be made, we suggest coding all patients upon whom postmortems were performed, as this seems to be one of the most important items, although it was omitted entirely in this volume.

MARGARET A. HALLOCK

History of the School of Nursing of the Presbyterian Hospital, New York, 1892-1942. By Eleanor Lee, R.N. Octavo of 286 pages, illustrated. New York, G. P. Putnam's Sons, 1942. Cloth, \$3.50.

This history of the nursing school of the Presbyterian Hospital in New York, published on the occasion of the fiftieth anniversary of its founding, is an interesting contribution to the history of nursing and the nursing profession in America.

GEORGE ROSEN

Emergency Care. By Marie A. Wooders, R.N., and Donald A. Curtis, M.D. Octavo of 560 pages, illustrated. Philadelphia, F. A. Davis Company, 1942. Cloth, \$3.50.

This work is a well-planned and orderly presentation of a highly important and often neglected subject. The thoroughness with which all types of accidents are covered is to be commended. The volume reads easily and any topic is readily located because of the intelligent arrangement of the material.

Chapter XIX, entitled "Mental Emergencies," is particularly recommended and might better have been used as Chapter I.

The latter third of the volume may be apropos of the times, but we do not believe a detailed account of the organization of our armed forces is part of a textbook on emergency care. It is interesting, terse, and also well-presented but out of place.

ESTABLISHED 1889

THEODORE W. NEUMANN, M.D., Phys.-in-Chg.
CENTRAL VALLEY, Orange County, N. Y.

GLENMARY SANITARIUM

For individual care and treatment of selected number of Nervous and Mental cases, Epileptics, and Drug or Alcoholic addicts. Strict privacy and close cooperation with patient's physician at all times. Successful for over 50 years.

ARTHUR J. CAPRON, *Physician-in-Charge*

OWEGO, TIOGA CO., N. Y.

HALCYON REST

764 BOSTON POST ROAD, RYE, NEW YORK

Henry W. Lloyd, M.D., *Physician-in-Charge*

Licensed and fully equipped for the treatment of nervous, mental, drug and alcohol patients, including Occupational therapy. Beautifully located a short distance from Rye Beach. **TELEPHONE: RYE 550** Write for illustrated booklet.

BRUNSWICK HOME

A PRIVATE SANITARIUM. Convalescents, postoperative, aged and infirm, and those with other chronic and nervous disorders. Separate accommodations for nervous and backward children. Physicians' treatments rigidly followed. C. L. MARKHAM, M.D., Supt.

B'way & Loudon, Ave., Amityville, N. Y., Tel: 1700, 1, 2

DR. BARNES SANITARIUM STAMFORD, CONN.

45 minutes from N. Y. C. via Merritt Parkway

For treatment of Nervous and Mental Disorders, Alcoholism and Convalescents. Carefully supervised Occupational Therapy. Facilities for Shock Therapy. Accessible location in tranquil, beautiful hill country. Separate buildings.

F. H. BARNES, M.D., Med. Supt. *Tel. 4-1143

WEST HILL

West 252nd St. and Fieldston Road
Riverdale-on-Hudson, New York City

For nervous, mental, drug and alcoholic patients. The sanitarium is beautifully located in a private park of ten acres. Attractive cottages, scientifically air-conditioned. Modern facilities for shock treatment. Occupational therapy and recreational activities. Doctors may direct the treatment. Rates and illustrated booklet gladly sent on request.

HENRY W. LLOYD, M.D., *Physician in Charge*
Telephone: Kingsbridge 9-8440

[Continued from page 282]

The author of this concise and readable introduction to the neuroses and psychoses has rendered a signal service to the medical profession. In the reviewer's opinion, he has succeeded in clarifying through the use of simple and descriptive language a readily grasped working knowledge of nervous and mental disorders. Pertinent use of illustrations clarifies neurophysiological and psychopathological conceptions. Treatment is briefly reviewed, mention being made of historical as well as modern methods.

It is highly recommended to those seeking a quick orientation in the field of neuropsychiatry.

FREDERICK L. PATRY

Diseases of Women. By Ten Teachers. Under the direction of Clifford White, M.D. Edited by Sir Comyns Berkeley, Clifford White, and Frank Cook. Seventh edition. Octavo of 435 pages, illustrated. Baltimore, Williams & Wilkins Company, 1942. Cloth, \$6.00.

Twenty-three years have elapsed since the first edition of this textbook appeared, and now the new seventh edition has been published. Such a book needs no introduction. It is well known, as are the authors.

Time has made changes in the original list of contributors, but the places of the two men who have retired have been taken by other eminent teachers.

War conditions have scattered this group of authors, but, in the compilation of the text, the material was all submitted to the individual writers for their criticism and correction, so that this edition, like those of former years, represents the combined ideas of ten eminent teachers.

The book entirely covers its title subject. The volume is of moderate size, concise, and clear. The introduction of the sulfonamides has made it necessary to rewrite the description of the treatment of most inflammatory conditions affecting the pelvis and urinary tract. The sections dealing with the anatomy of the pelvic organs and the physiology of menstruation have been fully revised, and a simple classification of ovarian tumors and uterine polypi has been introduced. This small textbook is worth while, and it should continue to be widely read.

WILLIAM SIDNEY SMITH

Carcinoma and Other Malignant Lesions of the Stomach. By Waltman Walters, M.D., Howard K. Gray, M.D., and James T. Priestley, M.D. Octavo of 576 pages, illustrated. Philadelphia, W. B. Saunders Company, 1942. Cloth, \$8.50.

This is a careful analysis and critical study of 11,000 patients of the Mayo Clinic for whom a diagnosis of malignant disease of the stomach had been made from 1907 to 1938, inclusive. Of these, 6,352 underwent operations, of which 2,840 were resections. Besides the three names on the title page, there were some 16 other contributors from among the associates in the Mayo Clinic and the Mayo Foundation.

The conclusion arrived at after this study is that "the treatment of malignant disease of the stomach of all types is surgical." Methods of diagnosis and differential diagnosis are evaluated, pathology discussed, pre- and postoperative treatment emphasized, and the types of surgical approach which have had the greatest application and success are explained and amply illustrated. There are 42 pages of statistical tables and graphs. Such a study of so great a number of cases under some sort of continuous supervision has, of course, a high

HANDWRITING DIAGNOSIS

in a December issue of the *New York Journal Commerce*, a need for handwriting analysis was brought to light.

According to the publication, handwriting analysis is being increasingly employed by war production plants in order to place employees more accurately where they are better qualified for through latent ability and temperament. It is also used to determine any inherent weakness of character and moral standards.

So great has been the demand for such analytical service of one of the country's best-known experts engaged solely in commercial analyses, that he had moved to the West Coast in order to serve his clients more promptly.

As explained by the personnel director of a large plant, competent handwriting analysis discloses traits of temperament which would tend to retard the advancement of one employee to a position highly questionable, yet, on the other hand, might indicate that such a worker could be effectively trained for any mechanical job of responsibility other than one for training or supervising others. Such knowledge, it was stated, has been of superior value in connection with that eloped by other types of psychological or IQ tests and has saved the company much valuable time and money.

See Your Travel Agent

Because of present conditions, the man who has to travel needs to keep informed about the problems encountered in transportation, hotel accommodations, etc. With the fast moving events and sudden changes, it is not always possible for the average person to keep abreast of current news.

To get information in a hurry and to get much needed help in making arrangements for transportation and hotel accommodations, the travel agent is still the traveler's best aide.

The travel agent is a highly trained specialist in his field. He can get you there if it is at all possible. He knows the hotels and resorts best suited to his clients' needs. He knows all transportation routes, railroad and bus schedules and, if needed, hotel floor plans, accommodations, rates, etc. The only compensation the travel agent expects for his service is the 10 per cent paid him by hotels and this compensation does not increase the cost to the traveler.

Wine in Diabetes Mellitus?

(Read this
free booklet)

AN authoritative summary, "The Therapeutic Uses of Wine," has been prepared in monograph form to answer such questions as this. In it, qualified and competent medical authorities review the pertinent scientific literature of present-day medicine. You are invited to write for this monograph.

The contents include sections on wine as a food and on the actions of wine on the gastrointestinal system, the cardio-vascular system, the genito-urinary system, the nervous system and the muscles, and the respiratory system. The uses of wine in diabetes mellitus, in acute infectious diseases and in treatment of the aged and convalescent are also discussed. The value of wine as a vehicle for medication is dealt with, and an important section on the contraindications to the use of wine is included. An extensive bibliography is presented for those who may wish to pursue the subject further.

This review results from a study supported by the Wine Advisory Board, an agricultural industry administrative agency established under the California Marketing Act, and has been sponsored by the Society of Medical Friends of Wine.

Members of the medical profession are invited to write for this monograph. Requests should be made to the Wine Advisory Board, 85 Second Street, San Francisco

[Continued from page 285]

ment of Health and the Board of Education of New York City. Dorothy B. Nyswander, Ph.D., Director of the Study. Octavo of 377 pages, illustrated. New York, The Commonwealth Fund, 1942. Cloth, \$2.00.

Widespread dissatisfaction has been expressed with school health programs by health and educational workers for a variety of reasons but chiefly because their practice does not match up with the underlying theory. A series of studies made during the past fifteen years has shown the need of knowledge not only of the kind, volume, and distribution of such services but also of their shortcomings in terms of end results. This book is really a culmination of these studies and contains an accounting of a four-year period of school health services in the Astoria district of New York City. The work was carried out by a Special Study Staff under an advisory committee and was sponsored by the Department of Health and the Board of Education.

The Astoria study group, working harmoniously together, examined the various aspects of school health services, determined the faults of the methods in current use, tried out new methods, and subjected the results obtained to a most detailed and painstaking analysis of all factors concerned. A strong conviction activated and directed this group in that they visualized school health services as being capable of providing a vital protective agency whose procedure could and must be improved. Their results as reported in this publication show the methods. They have introduced many improvements—priority in examination for children most in need, elimination of long delays in securing corrective attention, a more thorough examination, an increased sense of parent responsibility in health care as well as private physician interest, a greater utilization of available dental services, the establishment of a cooperative procedure of staff education and of suitable records.

Dr. Nyswander, the Director of the Study, and Dr. Philip Van Ingen and Dr. George T. Palmer, chairman and secretary, respectively, of the advisory committee, have contributed to the study of public health by the completion of this work.

JOSEPH C. REGAN

Health Education of the Public. A Practical Manual of Technic. By W. W. Bauer, M.D., and Thomas G. Hull, Ph.D. Second edition. Octavo of 315 pages, illustrated. Philadelphia, W. B. Saunders Company, 1942. Cloth, \$2.75.

This book covers all phases necessary for presentation of the subject of health and its widest aspects to the layman. The use of exhibits, pamphlets, lectures, and the radio are fully discussed, and examples of their use are carefully elucidated. The material in this book should be familiar to the chairmen of committees in all medical societies interested in the subject of public health and health education in general.

BENJAMIN M. BERNSTEIN

The Medical Clinics of North America. Volume 26, No. 4. July, 1942. Octavo of 1,345 pages, illustrated. Philadelphia, W. B. Saunders Company, 1942. Published Bi-Monthly (Six Numbers a Year). Cloth, \$16 net; Paper, \$12 net.

Stressing industrial medicine, this volume of the *Clinics* gives an excellent summary of the more important aspects of sickness in factories. Employment and pre-employment examinations, compensation, tuberculosis, lead poison, dermatitis, and psychiatry as applied to industry are all covered.

ANDREW M. BABEY

SORPARIN acts on the liver cells

DISTINCTIVE in the field of hepato-biliary therapy, Sorparin—Extract of *Sorbus aucuparia* "McNeil"—has amply demonstrated its clinical effectiveness in the treatment of—

Chronic Cholecystitis
Post-surgical Biliary Disease
Hepatitis
Prothrombin Deficiency

In chronic cholecystitis (proven by cholecystography, duodenal intubation, and surgery) complete relief of symptoms with Sorparin was obtained in 36 per cent, partial relief in 36 per cent, and no relief in 28 per cent of the cases receiving 18 grains daily. (Shinowara, G. Y., DeLor, C. J., and Means, J. W.: J. Lab. and Clin. Med., 27: 897-907 [April] 1942.)

Available in tablet form. Each tablet contains Ext. *Sorbus aucuparia* "McNeil" three grains.

Supplied in bottles of 100, 500 and 1000.

McNeil Laboratories
Incorporated
 Philadelphia - Pennsylvania

SORPARIN

Clinical Effectiveness

• Ortho-Gynol Vaginal Jelly has been found effective and acceptable, as prescribed by physicians for the control of conception. These findings are based on published material and reports from controlled research projects, covering an aggregate experience equivalent to thousands of woman-years, in which the jelly was used alone or with a mechanical device.

The facts thus adduced are further substantiated by the thousands of physicians who have employed Ortho-Gynol in their office practice and by the many clinics which are now dispensing Ortho-Gynol to their patients.

THE EMPIRE STATE'S CONTRIBUTION TO THE MEDICAL PROFESSION

For modification of measles . . .

IMMUNE GLOBULIN (HUMAN) *Lederle*

THE USE OF IMMUNE GLOBULIN is now considered the most practical and easily available means to attenuate measles; and, when indicated, to prevent its onset.

In a recent report¹ of an epidemic of measles in a child-caring institution, 91 cases of measles developed among 102 susceptible children ranging in age from 1½ to 10 years. The investigator found that immune globulin (human) modified the measles attack; also, there were no complications and no reactions. Moreover, it was observed that the course of the

disease was milder in the group receiving 4 cc. intramuscularly, as compared with those given 2 cc.

The opinion that measles is not a serious disease should be dispelled². The seriousness of complications, particularly bronchopneumonia, which may arise when the disease is allowed to run its course, justifies interference.

"IMMUNE GLOBULIN (Human) *Lederle*" has a uniformly high antibody titer; a low protein content; and is a clear, transparent solution.

COLLOIDAL *VS* IONIZABLE IRON IRON

The iron-protein of OVOFERRIN is non-irritating, highly assimilable

Iron salts' ions may irritate stomach and intestines.

For tonic action in the ELDERLY Patient

THE REQUIREMENTS of a hematonic and tonic in elderly patients are exacting

1. It must not disturb the digestion. 2. It must not constipate. 3. It must be readily assimilable. 4. It must stimulate the appetite. 5. It must be palatable and pleasant to take. 6. It must be free from extraneous coating or masking substances which may affect the dietary management of certain cases.

OVOFERRIN fulfills these requirements adequately and well because of its unique *colloidal* form. Unlike the ionizable iron salt preparations, it is *not* split up by the gastric juice with release of astringent and irritating ions. Also unlike the iron salts (citrate, sulphates, etc.) it

does not form dehydrating and constipating precipitates which may be difficult to assimilate. It arrives in the intestine as a stable, fully hydrated, colloidal oxide which is readily assimilated.

In over 40 years of world-wide use, it has been observed that OVOFERRIN is not only a rapid blood builder but actually stimulates the appetite and improves the well-being. It is palatable, odorless, and non-staining but it does not rely on sweetening, masking, or coating to achieve these properties. They are inherent in its colloidal state. Dose—one tablespoonful in a little milk or water at meals and bedtime.

Degalol

THE ORIGINAL DEOXYCHOLIC ACID

for fat digestion and the absorption of fat-soluble vitamins

Degalol represents deoxycholic acid, the bile acid which is chiefly responsible for emulsification of food fat and the formation of the water soluble choleic acid compounds.

Degalol is valuable in biliary fistula, assuring fat digestion even with diversion of bile to the outside. Degalol enhances absorption of the fat-soluble vita-

mins A, D, E, and K. In complete biliary obstruction with poor or absent fat digestion, Degalol makes possible utilization of food fat, and insures absorption of orally administered vitamin K.

Degalol consists solely of chemically pure deoxycholic acid. It is supplied in boxes of 100 1½ gr. tablets.

Riedel - de Haen, Inc. NEW YORK, N. Y.

Help wanted for Women at Work

Today, more and more women man factories, mills, offices . . . many of them unaccustomed to the strain of industrial jobs.

Result: fatigue, too frequent "rests", slowed production, "absenteeism" . . . much of it traceable to poor body mechanics.

In the *relief of certain types of workers' fatigue*, Camp Supports play an increasingly important role. For these supports are *designed along anatomical lines*; they lessen back strain and protect against sprain.

It is a matter of medical record that these supports have—for 30 years—successfully aided men and women to achieve better posture . . . hence to feel more fit . . . do more work with less fatigue.

S. H. CAMP & CO., Jackson, Mich.

"CORE-ECTOMY" ON TOMATOES

-For Kemp's SUN-RAYED Tomato Juice

"Not worth the expense," some tomato juice manufacturers might say—but *we* consider the removal of cores an exceedingly important process in Kemp's Sun-Rayed Tomato Juice. For tomato cores *are* bitter to the taste—not to be tolerated in the tomato juice which was originated for infant feeding, and which is used and recommended by more New York physicians than any other brand. Non-separating, full-bodied because of Kemp's patented process No. 1746657, which also insures high retention of vitamins A, B, and C.

A New Peptic Ulcer Therapy with Special Indications

Wyeth's Phosphaljel*, Aluminum Phosphate Gel, is a *special* preparation for use in the treatment of peptic ulcer. Phosphaljel has been found to be effective in gastrojejunal ulcer,¹ which has been called the most resistant type of peptic ulcer.²

Phosphaljel was first employed in an attempt to prevent postoperative jejunal ulcer in Mann-Williamson dogs. With Phosphaljel, ulcers were prevented in twenty of twenty-three Mann-Williamson animals;

furthermore, in a group of animals which developed Mann-Williamson ulcers, the administration of Phosphaljel caused complete healing of the ulcers in nine of ten cases.¹

These striking results led to the successful use of Phosphaljel in the treatment of peptic ulcer in man and disclosed its special usefulness in those cases of peptic ulcer associated with a relative or absolute deficiency of pancreatic juice, diarrhea or a low phosphorus diet.¹

GASTROJEJUNAL ULCER. Most difficult of all to treat satisfactorily—are gastrojejunal ulcers². In these highly resistant lesions Phosphaljel has been found to be effective. Gastrojejunal ulcers may occur after surgical procedures such as that shown below.

PHOSPHALJEL

Wyeth's ALUMINUM PHOSPHATE GEL

Dose: One or two tablespoonfuls every two hours, during the active stage of the ulcer. Later in the course of management, three tablespoonfuls with meals and at bedtime, or two tablespoonfuls six times daily with and between meals.

Where's all the energy coming from?

LOOK back, if you will, at your practice of a few years ago.

Where are those patients who "couldn't get a thing to do"?

Where are those workers who punched their time clocks only three or four times a week?

It's a different world now. There's more work to do than there are people to do it.

So nearly everyone is working harder and longer. With the result that food-energy requirements are higher. Almost doubled in some cases. For the Food and Nutrition Board of the National Research Council now recommends a daily intake of 4,500 calories for an active male.

This is where the physician's knowledge of the value of

bread can be most important to his patients—particularly in the face of shortages in other foods.

Bread is one of our best sources of food-energy. It is rich in carbohydrates, protein and, when made with milk, calcium. And white bread, which most people like best, now contains extra quantities of thiamin, niacin and iron.

So in these days, we believe you will find it desirable to include more bread in your recommendations to your patients. It fits the needs of the times—tastes good—satisfies hunger.

More than ever, bread is one of the fundamental foods in every normal diet.

Bread is basic

The Supreme Court Decision

Most physicians will probably never read the full text of the unanimous decision of the United States Supreme Court upholding the conviction of the American Medical Association and the Medical Society of the District of Columbia of a conspiracy to violate the Sherman Antitrust Law. It will remain to them an academic matter, as vague as the personality of Mr. Sherman himself, and as imponderable as the things which the decision itself does not appear to decide; so much legal spinach, as it were, and to hell with it. For this attitude no one can blame them. They have been trained not for the law but for the practice of medicine, which they still consider, rightly or wrongly, a profession. In so far as the Supreme Court has left undecided the question whether a physician's practice is "trade" within the meaning of Section 3 of the Sherman Act, there still exists a reasonable presumption that the practice of medicine is essentially a profession with, maybe, business contacts around the edges, contacts which will likely become more numerous as cooperatives increase numerically. Concerning this question, trade or profession, "In the light of what we shall say with respect to the charge laid in the indictment," said Mr. Justice Roberts, "we need not consider or decide this question."

Concerning the cooperative, Group Health, Inc., however, the Court remarked: "The fact that it is cooperative and procures services and facilities on behalf of its members only does not remove its activities

from the sphere of business." In its relationship to cooperatives as exemplified by Group Health, Inc., it would appear to be of no materiality whether medicine is a trade or a profession. For the Court held "the calling or occupation of the individual physicians immaterial if the purpose and the effect of their conspiracy was . . . obstruction and restraint of the business of Group Health."

Cooperatives are businesses, in other words, and whatever relationships the profession of medicine has with them are business relationships and are subject to the provisions of Section 3 of the Sherman Act, regulating these relationships. The right of the public to establish cooperatives is presumably upheld, and the right of such cooperative business to hire doctors on their own terms and the right of physicians to organize into groups and to receive payment by any method of their choice are also presumably upheld.

The profession of medicine does not enjoy immunity as do the labor unions by reason of the Clayton Act or the Norris-LaGuardia Act, from prosecution under the Sherman Act. Why should it? We have never yet heard a convincing argument to prove that it should. Why should it be permitted to restrain business or trade? The chief concern of organized medicine should be the maintenance of standards of professional conduct and practice. As long ago as 1931, Dr. William H. Ross, president of the Medical Society of the State of New York,

Pneumonia—A Secondary Disease

In former years the teaching was that pneumonias were either primary or secondary.¹ The latter, usually bronchopneumonia, followed already existing diseases, such as measles, whooping cough, influenza, etc. The primary pneumonias, chiefly lobar pneumonia, were largely attributed to the pneumococcus present in the upper respiratory tract, which descended to the lung after exposure to cold or because of other factors that lowered resistance. In recent years this concept has undergone considerable alteration.

We now realize that all forms of bacterial pneumonia are generally not primary. In nearly every case lobar pneumonia is preceded by the common cold, influenza, or some other virus adversely affecting the respiratory mucous membrane.^{2a} Colds, in turn, are caused by a virus which paves the way for invasion of secondary bacteria.^{2b} Similarly, the influenza virus predisposes to secondary infections.^{2c}

In the 1918 pandemic influenza, the most frequent secondary pneumonic invader was the *Streptococcus hemolyticus*, giving a characteristic clinical and pathologic picture.³ This organism, however, was not the only secondary invader. Numerous instances of pneumococcus,⁴ staphylococcus,⁵ and Pfeiffer's bacillus pneumonias⁶ were recorded during this epidemic. It is now realized that there is a synergism between the influenza virus and other bacteria, such as those enumerated.

Recent advances in the study of viruses have furnished additional facts regarding this synergism. Methods of culturing and isolating viruses during the primary infection have been devised. In the presence of the complicating pneumonia, the serums of the patients can be titrated for

neutralizing and complement fixing auto-virus antibodies. By such means it has been verified that pneumonias of different types are generally preceded by virus infections.⁷ In the New England studies, staphylococcus pneumonias were very prevalent, this organism following in the wake of an influenza A infection.⁷

Summing up the evidence, we can conclude that, with some exceptions, pneumonia is a secondary and not a primary disease. The exceptions are pneumonias due to the primary virus infection, to certain bacilli such as *Bacillus tuberculosis* and *tularensis*, and the mycoses. It seems clear that organisms find fertile soil in the lungs of patients stricken with influenza or a kindred virus infection. The secondary invader and the prevalent secondary pneumonia will depend on which organism is widely entrenched in the upper respiratory tracts of the community. In the presence of this train of events, chemotherapy may be advisable, not for the treatment of the initial virus disease (for that is ineffective), but prophylactically as an attempt to thwart the secondary invaders.

Intravenous Alimentation

There are times in disease, usually transient, when oral feeding is either undesirable or distinctly harmful. Intractable vomiting and diarrhea, particularly in infancy, and postoperative conditions and complications, especially of the gastrointestinal tract, are frequent examples. In such circumstances the institution of parenteral feeding spares and rests the gastrointestinal tract, permitting a more rapid restoration to normalcy.

For many years it has been a common practice to administer saline solutions intravenously. Glucose has been added to such solutions or, if preferable, simply given in distilled water in a concentration determined by the disturbed

chemistry of the body.¹ However, even if huge amounts of glucose solutions are given intravenously, it is impossible to supply the daily caloric needs solely by this method. To compensate for the quantitative deficiency in this type of feeding emulsions of fat have been injected by vein.² This addition still left unsolved the nutritional deficiencies caused by the absence of protein and vitamins. Elman and Weiner,³ by the intravenous administration of pure amino acids, supplied the missing protein stepping stones. They employed a 2 per cent solution of amino acids derived from the hydrolysis of casein, to which was added 2 per cent of tryptophan and cysteine, the missing essential

wrote:¹ "Organized medicine suffers from several weaknesses. One of them is the aloof relationship to health administration and to various health activities of a multitude of social organizations.

"Social changes will continue to increase in America, and social organizations to meet social needs will become more and more active. It will be better for the future position of the profession of medicine to guide the advent of these activities; determine their soundness and give them leadership in medical matters. Health activities of social organizations and the state must be considered as expressions of social medical need. It will be better to recognize and help to meet the problem than it will be to find something wrong with our relationship to it and then have to try to change that after the solution of the problems has passed the formative stage.

¹ Medical Times and L.I. Medical Journal (March) 1931.

Status of Physicians, 1942

During 1942, according to the *J.A.M.A.*,¹ 3,328 physicians died in the United States and Canada, but 5,163 graduates of medical schools in the United States were added. Excluding graduates of foreign schools first licensed in this country in the same year, the net gain in personnel to the profession stood at 1,952.

Of the three thousand and more deaths, heart disease again accounted for the greatest number. Coronary thrombosis and occlusion, other coronary diseases, and angina pectoris continued to lead the list, with cerebral hemorrhage, arteriosclerosis, and cardiovascular renal disease and chronic nephritis following close behind. The average age at death from all causes was 65, 0.9 per cent lower than in 1941 for a comparable number of deaths.

The year 1942 was not one of extraordinary pressure for physicians. Nor were deaths in military service to the number of 48 exceptionally high. Yet the toll of cardiovascular disease again heads the list of causes of death. It seems obvious that pressure of work on the physician age groups of 45 to 64 and 65 to 79 will increase during

"The profession of medicine does not always realize that it is not organized for administrative purposes, even though it is the only authoritative source of medical knowledge and the only group competent to give technical medical service. . . . It is medicine's obligation to furnish leadership, and in leadership rests the future position of medicine in public opinion." That was in 1931. It is now 1943.

Opportunity is still open to us. But for how long? It would be well to heed what Professor Bridgman of Harvard University said before the American Physical Society: ". . . scientists are curiously obtuse as to the social conditions which make possible their existence as a class. It is by no means a certainty that society will so evolve that the individual will be allowed to engage in independent intellectual activity. . . ." What say you, physicians?

the current year. What effect can be anticipated on the death rate from cardiovascular disease? In 1942, the number of deaths from all causes in these brackets was 45 to 49, 104; 50 to 54, 175; 55 to 59, 278; 60 to 64, 415; 65 to 69, 551; 70 to 74, 348; 75 to 79, 369. What will they be in 1943?

The loss in trained skill represented by this group is enormous. It is also the group upon which civilian medical service is chiefly dependent. Is it a proper function of organized medicine to study this group with the end in view to salvage all possible trained skills? Is the death rate in this group as low as it can be? Are some of these deaths preventable? If a study of this sort is not a proper function of organized medicine, of what agency is it a proper function? If skills at the present time of war are being unnecessarily wasted, and especially medical and surgical skills, whose concern should it be?

There is no such thing as a synthetic physician or surgeon. There is no such thing as synthetic experience in medicine. To what extent is salvage possible in this group? The present time of national necessity seems to us appropriate for a study of these questions. Is anybody interested?

¹ *J.A.M.A.* 121: 3 (Jan. 16) 1943.

SOME DIFFERENTIAL POINTS IN THE DIAGNOSIS OF ATYPICAL PNEUMONIA OF PROBABLE VIRUS ORIGIN

ANNE M. BAHLKE, M.D., Albany, New York

SINCE mid-August of 1942 the incidence of pneumonia of all forms as reported to the New York State Department of Health has been well above the five-year average for 1937-1941. A large proportion of this excess is attributable to cases regarded by the attending physician to be atypical and of obscure cause. Aside from one outbreak of this latter form of acute pneumonitis in a graduate school in an upstate city, no clear epidemics have been noted. There has been some tendency for the reported cases to be clumped in certain localities and more especially in the practices of certain physicians. Yet the reporting has been sufficiently widespread to make it clear that throughout the State as a whole physicians are conscious of and on the alert for this form of pneumonia.

The number of these cases reported weekly has mounted somewhat since the week in September when an article from the Bureau of Pneumonia Control appeared in the departmental weekly pamphlet, *Health News*, calling attention to the clinical aspects of the disease. Whether this increase is due to an actual increase in prevalence, or merely to an increasing awareness on the part of the profession, or both, cannot be ascertained. In either case the practicing physician is being faced more often with the problem of differentiating the atypical pneumonias from the more classical varieties and from grippe-like illnesses without pulmonic involvement. That such differentiation may be a difficult problem in individual cases is beyond question.

When the atypical disease assumes its usual pattern, one valuable differential point is established by the mode of onset. Instead of the sudden shaking chill with sharp pleural pain encountered so frequently in classical pneumococcal pneumonia, the patient with the atypical disease commonly complains only of insidious chilliness, and if he has discomfort in the chest it will be a sense of heaviness and soreness or aching, usually in the substernal region. At the same time he may become aware of an increasing malaise and a mild sore throat which is noticeable chiefly on swallowing. The latter symptom is rare in lobar pneumonia. Likewise rare is the headache which has been recorded so frequently and is often so severe in cases of atypical pneumonia.

In lobar pneumonia severe cough with char-

acteristic sputum is very likely to be one of the earliest symptoms. In atypical pneumonia several hours may elapse before coughing becomes established, but when it does it may be severe, paroxysmal, and highly intractable, even in the face of such effective medicaments as codeine or morphine. Most commonly it is dry in the early stages; later, mucoid or mucopurulent sputum in variable abundance may appear. Occasionally this sputum will be blood-streaked, but truly rusty or prune-juice sputum is not noted. Associated with the cough and probably partly responsible for it may be a severe grade of tracheitis.

Whereas the temperature mounts rapidly in classical pneumonia to a high level and stays high until defervescence begins, in atypical pneumonia the rise is likely to be slow and the level not maintained. Instead, the curve has a swinging contour, often with diurnal peaks, usually in the late afternoon or early evening. While levels of 104 F. or 105 F., and rarely even 106 F., have been recorded in the atypical disease, the majority of cases have only moderate fever of 101 F. or 102 F.; and occasional cases with characteristic x-rays have been presumably afebrile throughout. In lobar pneumonia fever is almost invariable. Furthermore, in lobar pneumonia recovery is most frequently by crisis; in atypical pneumonia a consistently lytic type of defervescence has been noted.

Accompanying the fever in the classical picture of pneumococcal pneumonia there is a proportional acceleration of the pulse rate. In a large percentage of atypical cases a relative bradycardia occurs.

Dyspnea and some degree of cyanosis are very common in the presence of the pneumonias of bacterial origin, even in cases in which the consolidation is not extensive. In the virus-type disease, on the other hand, both of these symptoms are relatively rare, and when they do occur the clinical picture is likely to be one of extreme severity in every other aspect as well. But even with severe disease and in the presence of definite respiratory distress, the respiratory rate is often not increased to the characteristically high levels of lobar pneumonia. Similarly, the delirium which is probably related to the anoxia of lobar consolidation has not been reported in the atypical disease.

In lobar pneumonia the fauces and pharynx may be somewhat suffused but for the most part they are not remarkable. In contrast to

From the Bureau of Pneumonia Control, New York State Department of Health, Albany, New York.

amino acids. By this method they were able to supply 2 Gm. of amino acid per kilo per day, an amount sufficient to establish a positive nitrogen balance. The development of the different vitamins in chemically pure form, adapted for parenteral administration, completed the chain of adequate intravenous alimentation.

Other investigators extended this method of feeding to correct specific deficiencies, such as the defective amino acid metabolism of nephrosis. Details and technics of administration have been carefully studied by these workers.^{4,5} More recently other conditions in which nitrogen equilibrium is difficult to achieve have proved amenable to intravenous alimentation.⁶ These latter investigators, by injecting amino acids intravenously, to the amount of 1 to 2 Gm. of nitrogen per hour, have attained nitrogen equilibrium in such varying diseases as malignant neoplasm, hyperthyroidism, chronic nephritis, cirrhosis of the liver, and chronic infections, such as chronic empyema.

In the past, parenteral feeding was poorly accomplished by the rectal or peritoneal administration of glucose and saline. These methods yielded pitifully few calories, and too frequently resulted in excessive abdominal distention. The injection of the necessary food elements by vein alone or in conjunction with vitamins injected subcutaneously or intramuscularly is a unique and invaluable addition to the therapeutic armamentarium in conditions demanding complete rest for the gastrointestinal tract or added quantities of one or more of the elements of nutrition

Correspondence

January 5, 1943

To the Editor:

Apropos of the high incidence of cancer among the Japs, as noted in the New York State JOURNAL recently, may I call attention to a note in a paper written by me* some time ago that "continuous grasp-

ing," and "greediness" were most potent factors in the genesis of stomach disorders, "including cancer."

Respectfully,

SMITH ELY JELLIFFE, M.D.
Hallett's Landing
Washington County, New York

Medical Officers Needed in Navy

The following communication has just been released by the Office of Naval Officer Procurement:

"In order to satisfactorily care for the medical and surgical needs of the increase in personnel to meet the requirements for the great expansion of the Navy, a larger number of medical officers is required. The present number of medical officers in the Navy must be greatly increased.

"There are vacancies to be filled in the ranks of Lieutenant (junior-grade), Lieutenant, and Lieutenant-Commander in the Medical Corps, and opportunities for promotion while on active duty.

"It is the policy of the Navy Department when specific needs arise to order medical officers for courses of instruction in various specialties.

"The following special courses of instruction for a limited number of medical officers in the Naval Reserve are now available: aviation medicine, medical duties with parachute troops, medical duties in deep diving, psychiatry, anesthesia, thoracic surgery, neuro-surgery, physical and fever therapy, and duties with epidemiology and laboratory units.

"Applications are accepted of those who do not meet the physical standards if their irregularities are not likely to be progressive or interfere with the performance of duty.

"NAVAL OFFICER PROCUREMENT
Medical Department
33 Pine Street, New York, New York
WHitehall 3-4060, Extension 13"

In the pure form of the virus-type pneumonia under discussion all the accepted sulfonamides have been tried and all who have used them agree that they do no good whatever. While there is no evidence that these drugs accentuate the disease process, there would seem to be little justification for their use in these cases because of the toxic reactions they may produce. In a few severe cases transfusions of convalescent and supposedly immune blood have been given, but there is no indication that these measures have had any appreciable effect on the disease.

When a case with the general picture attributed above to atypical pneumonia is encountered, pneumococcal pneumonia is by no means the only entity that must be ruled out of course. With severe forms of the disease miliary tuberculosis, acute rheumatic fever, typhoid fever, undulant fever, psittacosis, ornithosis, American Q fever, and even such conditions as subphrenic abscess may warrant consideration. With milder forms, the chief confusion comes from influenza, particularly under endemic conditions. In the latter disease the onset is usually more explosive, and constitutional symptoms are likely to be more marked, with aching of the back and extremities prominent among the initial symptoms. It will be recalled that in atypical pneumonia usually the only noteworthy aching is in the head and chest. Similarly the photophobia and pain on ocular motion so characteristic of influenza are seldom if ever encountered with atypical pneumonia. And the positive chest signs by physical examination and x-ray are lacking in uncomplicated influenza. Finally, with epidemiologic luck some indication of the incubation period may be given, and, if so, this has differential significance, since for influenza it is one or two days and for atypical pneumonia it is agreed by most authorities to run from twelve days to three weeks.

One thing that should stand out in the above discussion is the recurrent monotony of qualifying words and phrases such as "usually," "often," "maybe," and "in most cases." Such qualifications are important to remember whenever an attempt is being made to differentiate the virus-type pneumonia from clinically similar conditions. Considerable progress has been made toward a clarification of the clinical picture, but it is far from clear-cut as yet, and it is only when all the diseases mentioned take a typical form or the virus type occurs in epidemics, that differentiation of these entities can be made with any certainty. A differential diagnosis in any given case between atypical

pneumonia of probable viral cause and an atypical bacterial pneumonia, or between the virus-type disease and influenza, may never be possible. Probably the best principle to follow is not to make a definite diagnosis of virus-type pneumonia unless the clinical picture as described is accompanied by either physical or x-ray signs of pulmonic involvement. Some true cases will doubtless be disqualified in this way, but it is nevertheless the most scientific basis to work upon until such time as the causative agent has been identified and the clinical diagnosis can be properly confirmed by immunologic methods.

this is the situation frequently reported in atypical pneumonia—the fauces dusky red, the uvula swollen, the soft palate granular-looking, and the posterior pharyngeal wall markedly engorged, with a striking hypertrophy of the lymphoid tissue. Occasionally petechiae appear on the pharyngeal mucosa, and it has been thought by some observers that they are related to the severity of the cough and probably account for the blood-streaking of the sputum when it occurs.

Probably the most striking difference which exists between classical and atypical disease is encountered when consideration is given to the physical signs in the chest in these two conditions. There is no need to review the cardinal signs of lobar consolidation. It should be sufficient to say that the picture that those signs present is lacking in atypical pneumonia, so that there is seldom more than slight diminution of resonance and rales. The rales occur much more often than the dullness, but even they are not invariably present, and cases are on record in which definitely positive x-ray pictures have been found in the absence of any demonstrable physical signs. Rales, when present, are of the moist variety, fine, medium, or coarse. They may be numerous, but for the most part they are relatively few, and often they are heard only at the end of deep inspiration or after cough. In some cases rhonchi may be heard.

The patient with atypical pneumonia may occasionally look very sick, but even when he does, he seldom has the toxic appearance of the severely ill classical case; nor does he show the abdominal distention that so often accompanies the latter. Other gastrointestinal reactions, such as nausea and vomiting, may occur in either type of disease, but they are not prominent symptoms in either.

Herpes has been observed in atypical pneumonia, but with nothing like the frequency that it occurs when the illness is due to the pneumococcus. An erythematous eruption, on the other hand, virtually unheard of in untreated pneumococcal pneumonia, has on rare occasions been observed in severe cases of the atypical disease.

The characteristic x-ray shadow of pneumococcal lobar pneumonia is familiar to all. In virus-type pneumonia the lobar picture may be simulated closely, but for the most part the atypical trend that marks the clinical picture is followed roentgenologically as well. There is usually a diffuse increase of the bronchial markings and the first evidence of consolidation appears as a widening of the hilar shadows on one or both sides. Subsequently, the lesion spreads outward to the periphery and occasionally may

look solid, but usually it has a ground-glass or patchy appearance. Two or three lobes may be involved, and often the lesion appears to be regressing in one lobe at the same time that it is spreading in another. The x-ray usually becomes positive within the first week of illness and may clear within a few days or remain positive for several weeks. Ultimate complete clearing is the rule. In spite of the absence of pleural pain, if the right middle lobe is involved, thickening of the transverse pleura is occasionally seen. Actual effusion is very rare.

The moderate or marked leukocytosis that appears early in favorable cases of pneumococcal pneumonia is absent in the virus-type cases. These may show a slight elevation of white cells to 12,000–15,000 after the disease has been in progress for several days, but the early white count is usually normal, or there may even be an actual leukopenia.

A good sputum specimen from a case of pneumococcal pneumonia will usually show pneumococci in large numbers within twenty-four hours of the onset. Sputum from atypical pneumonia, on the contrary, shows only a mixed flora such as is found in pharyngeal secretions, and when pneumococci are present they are apt to be few in number and of the higher types.

The patient who has safely passed a crisis in a classical lobar pneumonia often returns to health at a surprising and gratifying rate of speed. The patient with the atypical disease may suffer from anorexia, profuse sweating, and weakness to a degree and for an interval out of all proportion to the apparent severity of his acute symptoms. And the acute febrile phase may be protracted so that two weeks or more may elapse even in mild cases before the patient may properly be regarded as convalescent; in many of the severe cases daily fever has persisted for three to four weeks. Such prolonged fever might be presumed to suggest the presence of secondary bacterial invasion and such foci should be watched for, but actually sequelae are rare.

Therapy with regard to virus-type pneumonia is in the symptomatic and supportive stage, and to date applications of the more specific agents have been uniformly unsuccessful. There is no reason to assume, of course, that anti-pneumococcal serum would be of benefit in the cases that do show pneumococci unless those micro-organisms are present in large numbers, and if they are, there is every likelihood that the patient does not have a virus-type pneumonia but rather an atypical case of bacterial origin. The brilliant results produced by sulfonamide drugs in classical pneumonia need no emphasis.

oratory tests may be employed to denote the major source of the hyperbilirubinemia. The hemobilirubin formed by the breakdown of hemoglobin by the cells of the reticulo-endothelial system gives the indirect van den Bergh reaction. The hepatic parenchyma converts this to cholebilirubin which gives the direct van den Bergh reaction. This test, therefore, can be used to distinguish between the jaundice produced by retention and that caused by regurgitation (Rich classification).¹ Thus, an indirect van den Bergh reaction in the presence of clinical jaundice is indicative of a hemolytic process; the test, however, will not distinguish between obstructive and hepatic types of jaundice.

Hemobilirubin ordinarily is retained by the kidneys but cholebilirubin, if present in the blood, is readily excreted in the urine. Urobilinogen is formed in the intestine by the bacterial reduction of bilirubin. It may be reabsorbed and excreted in the urine. The changes in the urinary pigments in the different types of jaundice are shown in Table 2. In hemolytic jaundice, urobilinogen without the presence of bilirubin in the urine is the rule. If biliary obstruction is complete, bilirubinuria without the presence of urobilinogen is encountered. Both pigments are present in cases of hepatitis or incomplete obstruction of the common bile duct. If the urinary excretion of urobilinogen is to be used as an indicator of the patency of the common bile duct, repeated tests should be made over a considerable period of time before a final decision is reached, since an acutely damaged liver may fail to secrete bile for several days and so mimic an obstructive jaundice.

Once hemolytic icterus is excluded, the problem usually confronting the clinician is whether to treat the patient surgically or medically. This question is primarily one of determining the patency of the common bile duct; in this clinic, duodenal drainage is frequently performed in order to obtain this information and the results have been of inestimable value in determining the necessity for surgical intervention.

Several metabolic tests have been proposed as an aid in differentiating between obstructive and nonobstructive jaundice. When the icterus is mainly obstructive in type, the galactose tolerance,² the cholesterol esters of the serum,³ and the conjugation of benzoic acid⁴ tend to be normal, while the serum phosphatase⁵ is increased. When jaundice is hepatic in origin and associated with parenchymal injury, the galactose tolerance, the cholesterol esters of the serum, and the conjugated benzoic acid all tend to be reduced, while the serum phosphatase is normal. Unfortunately, these various tests are not necessarily affected in the same way or to the same de-

* Considered, in the opinion of the authors, as important tests for hepatic function.

gree. Furthermore, a considerable proportion of cases are seen in which the result of any simple functional test is at variance with the apparent diagnosis. An extensive and controversial literature dealing with the diagnostic value and the comparative sensitiveness of this group of tests has arisen.

Much of this confusion has resulted from a failure to recognize the fact that the liver has a

THE FUNCTIONAL STUDY OF THE LIVER AND ITS CLINICAL EVALUATION

CARL H. GREENE, M.D., and MAURICE BRUGER, M.D., New York City

IT IS generally recognized that the liver has an enormous functional reserve and possesses what has been described as a "superabundance of tissue." Its activity is known to vary not only from day to day but also from hour to hour. Rarely does this organ work at full capacity for any length of time. However, the more the parenchyma of the liver is destroyed, the less the reserve and the greater the basic load. Fortunately for the sake of bodily economy, the liver has a marked regenerative capacity, perhaps the greatest of any organ in the body. Only in the presence of acute injury or of prolonged chronic disease do we find the parenchyma of the liver sufficiently destroyed to diminish the reserve and to produce evidence of hepatic insufficiency.

The liver has many functions, and no other organ is called upon to play such an active part in the maintenance of normal health. It has secretory, excretory, and metabolic activities. The secretion and excretion of bile with its content of bile salts, bile pigments, cholesterol, inorganic salts, and water is but one of the recognized functional activities of this organ. The importance of the liver in the maintenance of normal carbohydrate metabolism is common knowledge. It also plays an active part in the intermediary metabolism of fats and proteins. Its importance in the formation of the blood, particularly with respect to the plasma proteins, is well recognized. The liver, moreover, detoxifies various organic compounds which then are excreted in the bile or urine as relatively innocuous substances. The liver is the source of various enzymes such as amylase and small amounts of phosphatase, as well as many others which play an important part in the synthesis and mobilization of liver glycogen. No other organ in the body has such manifold activities, and it well deserves the title given to it by Mann—namely, "the commissariat of the body."

Obviously, therefore, there can be no single test for hepatic function which will measure all these activities. Individual tests, shown in Table 1, have been described which attempt more or less successfully to evaluate one or another of these functions. This table is by no means complete or comprehensive, but it serves to show the complexity of the problem and to

indicate the more important physiologic activities of the liver.

It is neither desirable nor practical to carry out more than a few of these functional tests on any one patient. The choice of the procedures to be utilized must not be haphazard since many of these have specific indications. Moreover, the results of such studies should supplement the clinical information obtained by a detailed history and a careful physical examination.

Functional Tests in Hepatic Disease with Jaundice

Jaundice is the outstanding clinical symptom indicative of disease of the liver or biliary tract. Patients with hepatic disorders, therefore, can be divided into two groups—those with and those without jaundice. It is generally recognized that icterus may be classified in three main groups: (1) the hemolytic type, (2) the hepatogenous type, and (3) the obstructive type. The terminology varies according to the classification used, but in general these three groups are fairly well defined. It should be emphasized, however, that only under exceptional circumstances is the jaundice uncomplicated in type. For example, the hemolytic icterus of patients with malaria or hemolytic anemia is frequently complicated by damage to the hepatic cells. Patients with carcinoma of the head of the pancreas probably present a picture of uncomplicated obstructive jaundice during the first few days of the obstruction, but thereafter parenchymal damage develops in consequence of obstruction and hydrohepatosis. Obstructive jaundice due to stones in the common bile duct is frequently aggravated by associated cholangitis and consequent damage to the hepatic parenchyma. Hepatogenous icterus or catarrhal jaundice has many obstructive features, as may be evidenced by the multiple thrombi present in the biliary canaliculi. Finally, the hemolytic jaundice occurring in the crisis of acute hemolytic anemia is not infrequently accompanied by the deposition of pigment stones in the biliary tract. It must be recognized, therefore, that in many patients with jaundice, the clinician is confronted with a diffuse disease of the liver, and the classification of the icterus into hemolytic, hepatogenous, or obstructive types merely represents the major element in its production.

Even though it will be agreed that uncomplicated forms of jaundice rarely occur, several lab-

the most effective method of combating the tendency to postoperative hemorrhage.

Functional Tests in Hepatic Disease Without Jaundice

The diagnostic problem is different in cases of chronic hepatic disease without jaundice. Three important conditions fall into this category—namely (1) cirrhosis, (2) chronic passive congestion, and (3) primary or secondary carcinoma. The excretory loading tests are of particular value in this group. In this institution, the bromsulfalein excretion test is favored because the dye is cheap, is readily obtainable, and rarely produces a systemic reaction after intravenous administration. This test, as proposed by Rosenthal and White,¹⁴ employed 2 mg. of the dye per kilogram of body weight. Greene¹⁵ increased the dosage to 5 mg. per kilogram. The larger amount of dye increases slightly the sensitivity of the test. Macdonald¹⁶ has modified this procedure by doing serial determinations of the bromsulfalein content of the serum after the intravenous administration of 2 or 5 mg. of the dye per kilogram of body weight. Recently, Mateer and his coworkers¹² claimed a greater sensitivity for the serial bromsulfalein test than for the original Rosenthal and White method.

Obviously, all excretory loading tests may be increased in sensitivity by augmenting the amount of material injected. It should be remembered, however, that the greater the sensitivity of the test, the more will physiologic factors influence the results. Thus, an associated anemia or a slight degree of circulatory insufficiency may give positive results if the excretory loading test is rendered too sensitive. For these reasons, we have preferred the original Rosenthal and White procedure, using the 5 mg. per

kilogram dose, since under these circumstances abnormal dye retention in the blood could be interpreted safely as indicating hepatic damage.

One of the factors in the production of ascites in patients with cirrhosis of the liver is the reduction in the serum proteins, particularly the albumin fraction. For the most part, the serum globulin remains unchanged and a reversal of the albumin/globulin ratio occurs. A number of tests have been introduced which attempt to measure this disturbance in the blood proteins such as the Takata-Ara reaction,¹⁷ the formol-gel test,¹⁸ the Weltmann coagulation band,¹⁹ the magnesium chloride test of Bauer,²⁰ and, more recently, the colloidal gold reaction.²¹

Of these, we prefer the Takata-Ara reaction since it is the simplest to do and is perhaps the most specific. If other conditions producing a reversal of the albumin/globulin ratio in the serum, such as Bright's disease, multiple myeloma, lymphogranuloma venereum, chronic infections like tuberculosis, etc., can be ruled out, the Takata-Ara reaction may be used in the differential diagnosis of chronic hepatic disorders without jaundice. Bromsulfalein dye retention may occur in chronic passive congestion of the liver, in primary or secondary carcinoma of the liver, and in hepatic cirrhosis, but the Takata-Ara reaction is negative in the first two conditions and almost always positive in the last.

Summary

Since the liver has many activities, there cannot be a single test for hepatic function. The individual tests proposed to measure these manifold activities have been classified and their specific indications noted. The value of the cephalin-cholesterol flocculation test in the differential diagnosis of hepatogenous jaundice

TABLE 2—THE VAN DEN BERGH REACTION AND THE EXCRETION OF BILE AND UROBILINOGEN IN THE URINE OF NORMAL SUBJECTS AND IN PATIENTS WITH DISEASES OF THE LIVER AND BILIARY TRACT WITH AND WITHOUT JAUNDICE

Cirrhosis (no jaun- dice)	=	=	=	+ + + +

large factor of safety so that extensive injury may not preclude a normal response to one or the other test. The different procedures are concerned with different physiologic activities and so need not be affected in either the same manner or same degree. It has long been accepted that the clinical picture in the various types of jaundice is not always distinct. The same confusion is true of the pathologic changes in many cases of chronic hepatitis of varying degrees of severity.

When the various interfering factors are taken into consideration, it becomes obvious that the clinical grouping of cases of jaundice into hepatic and obstructive types is arbitrary. The value of functional tests is not determined by the relative percentage of positive results in cases of hepatic and obstructive types of jaundice. The tests should, rather, be used in an attempt to determine the extent to which the various elements already discussed enter into the clinical picture.

The Cephalin-Cholesterol Flocculation Test*

In 1938, Hanger⁶ described the cephalin-cholesterol flocculation test as a laboratory procedure to be used in the differential diagnosis between obstructive and hepatogenous jaundice. Since then, Hanger,⁷ Hanger and Patek,⁸ Pohle and Stewart,⁹ Rosenberg,¹⁰ Rosenberg and Soskin,¹¹ Mateer and his coworkers,¹² and Lippman and Bakst¹³ have reported favorable results with this test.

Cephalin-cholesterol flocculation tests were carried out according to the original technic of Hanger in 27 patients with obstructive jaundice, in 62 with hepatogenous jaundice, in 19 with miscellaneous types of hepatic disease associated with jaundice, and in 52 with various non-hepatic diseases without icterus—a total of 160 tests. The results are given in Table 3.

* With the assistance of Drs. James R. McMillan and Hobart H. Todd.

This table shows that in early obstructive jaundice, the cephalin-cholesterol flocculation test was usually negative. Positive results, however, were observed in long-standing cases of common bile duct obstruction associated with obstructive biliary fibrosis. In hepatogenous jaundice, the test was positive in a large percentage of cases. In other types of hepatic disease without clinical jaundice, such as portal cirrhosis, chronic passive congestion, and Gaucher's disease, the flocculation test frequently gave positive results. A negative reaction was the rule in cases of chronic cholecystitis, as well as in the majority of control cases. Positive tests were also encountered in a few conditions in which neither jaundice nor a clinically recognizable disease of the liver was present. Of significance were the results obtained in 26 patients with rheumatoid arthritis, for 11 gave a 1 plus to 4 plus reaction. One can only conjecture as to the significance of this finding, but it is conceivable that rheumatoid arthritis, being an infectious disorder, may be associated at times with a mild diffuse hepatitis. It is of further interest to note the 4 plus reaction obtained in 3 patients with Gaucher's disease and in 2 with malaria.

Surgical Aspects

From the standpoint of the surgeon, the patients with obstructive jaundice present a distinct operative risk. Postoperative fatalities fall into two general headings—namely, hemorrhage and "liver death." Until recent years, death from postoperative hemorrhage was not uncommon. This is now known to result from a deficiency of prothrombin in the blood secondary to defective absorption of vitamin K from the intestinal tract. The blood prothrombin should be determined routinely in all patients with jaundice in whom surgery is contemplated; if low, the value should be checked repeatedly. Once the blood prothrombin has been brought to normal levels preoperatively and maintained at these levels postoperatively by adequate vitamin K therapy, the surgeon need no longer fear hemorrhage as a complication.

While the blood prothrombin of most patients with obstructive jaundice responds favorably to vitamin K therapy, a small number (probably less than 10 per cent) fail to show this response in spite of adequate parenteral administration of the vitamin. It is now recognized that this lack of therapeutic response is indicative of severe damage to the parenchymal cells of the liver. Operative interference in such cases should be postponed wherever possible until the hepatic damage is less extreme or, if undertaken, the seriousness of the condition must be fully recognized. Repeated transfusion of fresh blood then becomes

the most effective method of combating the tendency to postoperative hemorrhage.

Functional Tests in Hepatic Disease Without Jaundice

The diagnostic problem is different in cases of chronic hepatic disease without jaundice. Three important conditions fall into this category—namely (1) cirrhosis, (2) chronic passive congestion, and (3) primary or secondary carcinoma. The excretory loading tests are of particular value in this group. In this institution, the bromsulfalein excretion test is favored because the dye is cheap, is readily obtainable, and rarely produces a systemic reaction after intravenous administration. This test, as proposed by Rosenthal and White,¹⁴ employed 2 mg. of the dye per kilogram of body weight. Greene¹⁵ increased the dosage to 5 mg. per kilogram. The larger amount of dye increases slightly the sensitivity of the test. Macdonald¹⁶ has modified this procedure by doing serial determinations of the bromsulfalein content of the serum after the intravenous administration of 2 or 5 mg. of the dye per kilogram of body weight. Recently, Mateer and his coworkers¹² claimed a greater sensitivity for the serial bromsulfalein test than for the original Rosenthal and White method.

Obviously, all excretory loading tests may be increased in sensitivity by augmenting the amount of material injected. It should be remembered, however, that the greater the sensitivity of the test, the more will physiologic factors influence the results. Thus, an associated anemia or a slight degree of circulatory insufficiency may give positive results if the excretory loading test is rendered too sensitive. For these reasons, we have preferred the original Rosenthal and White procedure, using the 5 mg. per

kilogram dose, since under these circumstances abnormal dye retention in the blood could be interpreted safely as indicating hepatic damage.

One of the factors in the production of ascites in patients with cirrhosis of the liver is the reduction in the serum proteins, particularly the albumin fraction. For the most part, the serum globulin remains unchanged and a reversal of the albumin/globulin ratio occurs. A number of tests have been introduced which attempt to measure this disturbance in the blood proteins such as the Takata-Ara reaction,¹⁷ the formol-gel test,¹⁸ the Weltmann coagulation band,¹⁹ the magnesium chloride test of Bauer,²⁰ and, more recently, the colloidal gold reaction.²¹

Of these, we prefer the Takata-Ara reaction since it is the simplest to do and is perhaps the most specific. If other conditions producing a reversal of the albumin/globulin ratio in the serum, such as Bright's disease, multiple myeloma, lymphogranuloma venereum, chronic infections like tuberculosis, etc., can be ruled out, the Takata-Ara reaction may be used in the differential diagnosis of chronic hepatic disorders without jaundice. Bromsulfalein dye retention may occur in chronic passive congestion of the liver, in primary or secondary carcinoma of the liver, and in hepatic cirrhosis, but the Takata-Ara reaction is negative in the first two conditions and almost always positive in the last.

Summary

Since the liver has many activities, there cannot be a single test for hepatic function. The individual tests proposed to measure these manifold activities have been classified and their specific indications noted. The value of the cephalin-cholesterol flocculation test in the differential diagnosis of hepatogenous jaundice

from early obstructive jaundice is mentioned. The results of 160 such flocculation tests are given, and the sensitivity of the test in denoting damage to the parenchyma of the liver is indicated. It is concluded that laboratory procedures for studying the functional capacity of the liver are of distinct importance in the diagnosis and treatment of hepatic disease, providing such tests are properly selected and there is a clear understanding of their limitations.

"FOUNDATION PRIZE" CONTEST ANNOUNCED

Announcement has been made of the prize award contest held under the auspices of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons by the secretary of the Association, Dr. James R. Bloss. According to Dr. Bloss, the award is to be known as the "Foundation Prize." Rules governing the contest, which closes June 1, are as follows:

1. The award, which shall be known as "The Foundation Prize," shall consist of \$150.
2. Eligible contestants shall include only (a) interns, residents, or graduate students in obstetrics, gynecology, or abdominal surgery, and (b) physicians (with an M.D. degree) who are actively practicing or teaching obstetrics, gynecology, or abdominal surgery.
3. Manuscripts must be presented under a nom-de-plume, which shall in no way indicate the author's identity, to the Secretary of the Association, together with a sealed envelope bearing the nom-de-plume and containing a card showing the name and address of the contestant.
4. Manuscripts must be limited to 5,000 words and must be typewritten, double-spaced, on one side of the sheet. Ample margins should be provided. Illustrations should be limited to such as are

required for a clear exposition of the thesis.

5. The successful thesis shall become the property of the Association, but this provision shall in no way interfere with publication of the communication in the journal of the author's choice. Unsuccessful contributions will be returned promptly to their authors.

6. Three copies of all manuscripts and illustrations entered in a given year must be in the hands of the Secretary before June 1.

7. The award will be made at the Annual Meetings of the Association, at which time the successful contestant must appear in person to present his contribution as a part of the regular scientific program, in conformity with the rules of the Association. The successful contestant must meet all expenses incident to this presentation.

8. The President of the Association shall annually appoint a Committee on Award, which, under its own regulations, shall determine the successful contestant and shall inform the Secretary of his name and address at least two weeks before the annual meeting.

JAMES R. BLOSS, M.D., Secretary
418 Eleventh Street
Huntington, West Virginia

TO DISCUSS HEART FAILURE

Dr. Harry Gold, assistant professor of pharmacology, Cornell University Medical College, will discuss "The Management of Heart Failure" at the fifth session of the Refresher Lecture Course in Cardiovascular Diseases, which is being given under the joint auspices of the New York Academy of Medicine and the New York Heart Association, of

the New York Tuberculosis and Health Association. Dr. Gold's talk will be given on Wednesday, February 24, at 4:30 P.M. at the Academy of Medicine, 2 East 103 Street, and is open to all practicing physicians and medical students. Dr. Herbert Chasis, assistant professor of medicine, New York University College of Medicine, will preside.

A NEW APPROACH TO CROSS CYLINDER TESTS

JOSEPH I. PASCAL, M.D., New York City

ONE of the common methods of testing for astigmatism is by the use of some form of line chart, fan chart, clock dial, revolving cross, etc. The principle underlying the use of a line chart test is the fact that the retinal diffusion spot in an astigmatic eye is generally a line or an oval. But under certain conditions the retinal diffusion spot in an astigmatic eye is a circle. Under such conditions the line chart test is inapplicable, but it is precisely here that the cross cylinder test comes in. If the testing conditions are maintained so that the retinal diffusion spot is a circle throughout, then the complete test for astigmatism can be made in the same manner as a test made for a spherical error. The retinal diffusion spot in an astigmatic eye is circular when the astigmatism has been changed, by a sphere if necessary, to equally mixed astigmatism. The diffusion circle which lies about midway in the interval of Sturm is then on the retina, one focal line being in front of the retina and the other about the same distance behind the retina. The sphere which changes every type of astigmatism into equally mixed astigmatism is the so-called equivalent sphere, which generally gives best uncorrected vision.

Let us take a case of 1.00 diopter of astigmatism with the rule and refer our discussion and diagrams to this case. When the condition is changed to one of equally mixed astigmatism, we have 0.50 D. myopia in the vertical meridian and 0.50 D. hyperopia in the horizontal meridian. The retinal diffusion circles indicated by the letters "D.C." in the tables are 0.50 D. in each meridian and are equivalent to the diffusion circles in an eye with a half diopter of spherical error.

With the eye in this condition, the presence of astigmatism and the approximate axis can be ascertained or corroborated by the testing cross cylinder, the effect of which will be seen by reference to the tables. We shall try several powers of cross cylinder, and for the sake of convenience will mention in this discussion only the plus part of the cross cylinder. When the testing cross cylinder is set so that its axes coincide with the principal meridians of the astigmatism, we shall refer to it as a "principal setting." When the testing cross cylinder is set so that its axes are oblique to the principal meridians of the astigmatism, we shall refer to it as an oblique setting. In all cases there are two positions

designated as (A) and (B). In the "principal setting," for example, the plus 0.25 cylinder is at axis 90 in position (A) and at axis 180 in position (B). Of course, at the same time the minus component of the testing cross cylinder, the minus 0.25 C., is at axis 180 in position (A) and at axis 90 in position (B). For the sake of brevity we shall omit the constant mention of this in our discussion.

Table 1 shows the effects of different settings of several cross cylinders in our selected case of 1.00 diopter of equally mixed astigmatism. Twenty degrees off axis means for (A) plus cyl. ax. 70 - cyl. ax. 160, and for (B) plus cyl. ax. 160 - cyl. ax. 70. The same holds for the other angles. Suppose our testing cross cylinder was 0.25 C. ($\neq 0.12$) in the same setting, 20 degrees off axis—that is, plus cylinder axis 70 in position (A) and plus cylinder axis 160 in position (B). The resultant diffusion circles would be in (A) 0.42×0.42 and in (B) 0.60×0.60 , giving a spherical difference of 0.18. If our testing cross cylinder was 0.50 ($\neq 0.25$ C.) similarly set 20 degrees off axis, the resultant diffusion circles are in (A) 0.35×0.35 and in (B) 0.71×0.71 . The difference, which may be termed the spherical difference, S.D., equals 0.36. The patient will naturally prefer position (A), showing the presence of astigmatism and the approximate axis of the cylinder plus axis 70 (or minus axis 160). If our testing cross cylinder was 0.75 ($\neq 0.37$) in the same setting the diffusion circles would be in (A) 0.32×0.32 and in (B) 0.82×0.82 , giving a larger S.D., amounting now to 0.50 D.

While the diffusion spots are circular, the directions of their diameters corresponding to the direction of the resultant principal meridians vary in each case, and are indicated in a few instances in the table, in parentheses. It will be seen from Table 1 that the presence of astigmatism is brought out most readily when the testing cross cylinder is at or near the principal setting. The difference in the size of the diffusion circles is then at a maximum. We must also remember that the areas of the diffusion circles vary with the square of the diameters. For example, the difference in area between two diffusion circles whose diameters in terms of dioptric error are, respectively, 0.25 and 0.75 are as one to nine, whereas the diameters are as one to three. The spherical differences marked "S.D." in the tables refer only to the linear differences of their diameters. If we use a

TABLE 1.—1.00 D. ASTIGMATISM—CHANGED TO EQUALLY MIXED ASTIGMATISM

I. Applying 0.25 Cr. C. (± 0.12 C.)			
1. Twenty degrees off axis (A) + C. ax. 70; (B) + C. ax. 160	{(A) D.C. = 0.42×0.42 (B) D.C. = 0.60×0.60 }	S.D. = 0.18	(5-95°) (86-176°)
2. Ten degrees off axis (A) + C. ax. 80; (B) + C. ax. 170	{(A) D.C. = 0.39×0.39 (B) D.C. = 0.61×0.61 }	S.D. = 0.22	
3. Principal setting (A) + C. ax. 90; (B) + C. ax. 180	{(A) D.C. = 0.37×0.37 (B) D.C. = 0.62×0.62 }	S.D. = 0.25	
II. Applying 0.50 Cr. C. (± 0.25 C.)			
1. Twenty degrees off axis (A) + C. ax. 70; (B) + C. ax. 160	{(A) D.C. = 0.35×0.35 (B) D.C. = 0.71×0.71 }	S.D. = 0.36	(14-104°) (77-167°)
2. Ten degrees off axis (A) + C. ax. 80; (B) + C. ax. 170	{(A) D.C. = 0.28×0.28 (B) D.C. = 0.74×0.74 }	S.D. = 0.46	
3. Principal setting (A) + C. ax. 90; (B) + C. ax. 180	{(A) D.C. = 0.25×0.25 (B) D.C. = 0.75×0.75 }	S.D. = 0.50	
III. Applying 0.75 Cr. C. (± 0.37 C.)			
1. Twenty degrees off axis (A) + C. ax. 70; (B) + C. ax. 160	{(A) D.C. = 0.32×0.32 (B) D.C. = 0.82×0.82 }	S.D. = 0.50	
2. Ten degrees off axis (A) + C. ax. 80; (B) + C. ax. 170	{(A) D.C. = 0.21×0.21 (B) D.C. = 0.86×0.86 }	S.D. = 0.65	
3. Principal setting (A) + C. ax. 90; (B) + C. ax. 180	{(A) D.C. = 0.12×0.12 (B) D.C. = 0.87×0.87 }	S.D. = 0.75	
IV. Applying 1.00 Cr. C. (± 0.50 C.)			
1. Twenty degrees off axis (A) + C. ax. 70; (B) + C. ax. 160	{(A) D.C. = 0.34×0.34 (B) D.C. = 0.94×0.94 }	S.D. = 0.60	
2. Ten degrees off axis (A) + C. ax. 80; (B) + C. ax. 170	{(A) D.C. = 0.17×0.17 (B) D.C. = 0.98×0.98 }	S.D. = 0.81	
3. Principal setting (A) + C. ax. 90; (B) + C. ax. 180	{(A) D.C. = zero (B) D.C. = 1.00×1.00 }	S.D. = 1.00	
V. Applying 1.50 Cr. C. (± 0.75 C.)			
1. Twenty degrees off axis (A) + C. ax. 70; (B) + C. ax. 160	{(A) D.C. = 0.49×0.49 (B) D.C. = 1.18×1.18 }	S.D. = 0.69	
2. Ten degrees off axis (A) + C. ax. 80; (B) + C. ax. 170	{(A) D.C. = 0.33×0.33 (B) D.C. = 1.23×1.23 }	S.D. = 0.90	
3. Principal setting (A) + C. ax. 90; (B) + C. ax. 180	{(A) D.C. = 0.25×0.25 (B) D.C. = 1.25×1.25 }	S.D. = 1.00	

stronger cross cylinder, up to a certain point the difference in the size of the diffusion circles in positions (A) and (B) will be more marked.

In general, the difference in the size of the diffusion circle in positions (A) and (B), when testing for the presence of astigmatism and the approximate axis, depends upon three factors: (1) the amount of astigmatism, (2) the full strength of the cross cylinder, and (3) the angle at which the testing cross cylinder is set. The stronger the testing cross cylinder, as long as it is less than the amount of astigmatism, the more marked the difference between (A) and (B). The difference reaches its maximum when the testing cross cylinder equals the amount of astigmatism. In all these cases the difference in the size of the diffusion circles between (A) and (B) in the principal setting is equal to the full strength of the testing cross cylinder.

That is, when the testing cross cylinder is a quarter diopter, 0.25 C. (± 0.12 C.), the difference in the size of the diffusion circles is 0.25. When the testing cross cylinder is 1.00 D., 1.00 C. (± 0.50 C.), the difference will be 1.00 D. This is the limit in our case, since the total amount of the astigmatism is 1.00 D. The difference in the size of the diffusion circles can never be

more than the full amount of astigmatism. If a stronger testing cross cylinder is used, say 1.50 C. (± 0.75 C.), the difference in the size of the diffusion circle will still be 1.00 D. The practical bearing of this is to use a stronger rather than a weaker cross cylinder, preferably one approaching the amount of astigmatism. The best results are obtained when the testing cross cylinder is equal to the amount of astigmatism. In this case the comparison is most easily made as one D.C. is zero. The comparison is therefore made between a clear image and a blurred image rather than between two images, both blurred, but to an unequal extent.* In an oblique setting the difference becomes less and diminishes as the obliquity increases, until, when the obliquity is 45 degrees, there is no difference at all.

After the presence of the astigmatism and the approximate axis have been determined or verified, we then determine the accurate axis. The use of the cross cylinder for accurate axis position is considered by many its most valuable feature. This part of the test is also best made when the retinal diffusion spots in the two positions are of the same type—that is, circular. Otherwise, a comparison of the two positions is often

* The amount of blur in the better position may be judged from the visual acuity obtained.

TABLE 2.—EFFECT OF USING 0.50 DIOPTER CORRECTING CROSS CYLINDER (± 0.25)

2. Test. Cr. C. 1.00 (± 0.50 C.) axes, etc.			
(A) D.C. = 0.59 \times 0.59	(B) D.C. = 0.41 \times 0.41	S.D. = 0.18	

difficult. The patient may say that he sees both images blurred but in a different way. This is understandable because the retinal diffusion spots are different in the two positions, consisting of ovals of different orientation. But if the test is made so that the retinal diffusion spot is always a diffusion circle, merely differing in size in the two positions of the cross cylinder, it becomes easier for the patient to compare the two positions. The difference is comparable to the effect of changing the spherical power in a spherical error. This method is therefore in a sense a spherical approach to astigmatic corrections. We get this effect most easily if we make use of correcting cross cylinders, as suggested by Dr. Frank B. Smart, as well as of testing cross cylinders.

Suppose our initial test as shown in Table 1, with any of the cross cylinders, was applied 20 degrees off axis. Our approximate finding was then plus cylinder axis 70, -cylinder axis

160. Suppose we now insert a half diopter, 0.50 D. (± 0.25 C.), correcting cross cylinder with the plus cylinder axis 70, minus cylinder axis 160, and apply our testing cross cylinders at 45 degrees either way. This gives again in each case two positions which we call again (A) and (B). Table 2 shows the effect of using 0.50 diopter correcting cross cylinder (± 0.25), (this is probably the most serviceable cross cylinder to be used), with different powers of testing cross cylinders. In every case as position (B) gives the smaller diffusion circle and therefore better vision, the correcting cross cylinder has to be turned, the plus cylinder axis toward 90 until there is no difference.

Table 3 shows the effect of using different powers of correcting cross cylinders at several angles of obliquity and also different powers of testing cross cylinders, axes 45 degrees either way. It may be emphasized that throughout the test the patient compares images made up

TABLE 4—CORRECTING CROSS CYLINDER 0.50, OFF AXIS—
TESTING CROSS CYLINDER 1.00, 45 DEGREES AWAY

I. 20° off axis	
1. Astig. 0.50 D.	
S.D. = 0.66 - 0.35 = 0.31	
(0.42 - 0.11 = 0.31)	
2. Astig. 1.00 D.	
S.D. = 0.83 - 0.22 = 0.61	
3. Astig. 1.50 D.	
S.D. = 1.03 - 0.34 = 0.69	
(1.26 - 0.33 = 0.93)	
4. Astig. 2.00 D.	
S.D. = 1.25 - 0.54 = 0.71	
(1.67 - 0.44 = 1.23)	
II. 10° off axis	
1. Astig. 0.50 D.	
S.D. = 0.59 - 0.41 = 0.18	
(0.21 - 0.04 = 0.17)	
2. Astig. 1.00 D.	
S.D. = 0.71 - 0.39 = 0.32	
(0.42 - 0.08 = 0.34)	
3. Astig. 1.50 D.	
S.D. = 0.88 - 0.51 = 0.37	
(0.63 - 0.12 = 0.51)	
4. Astig. 2.00 D.	
S.D. = 1.09 - 0.71 = 0.38	
(0.85 - 0.17 = 0.68)	
III. 5° off axis	
1. Astig. 0.50 D.	
S.D. = 0.54 - 0.46 = 0.08	
(0.17 - 0.08 = 0.09)	
2. Astig. 1.00 D.	
S.D. = 0.64 - 0.48 = 0.16	
(0.34 - 0.17 = 0.17)	
3. Astig. 1.50 D.	
S.D. = 0.79 - 0.62 = 0.17	
(0.51 - 0.25 = 0.26)	
4. Astig. 2.00 D.	
S.D. = 1.00 - 0.80 = 0.20	
(0.68 - 0.33 = 0.35)	

of the same type of diffusion spots—namely, diffusion circles of different sizes.

It can be seen from a study of the tables that generally as the cylinder increases in strength, both the correcting and the testing cylinder, the diffusion circles increase and coincidentally the spherical difference increases. The latter increase, however, is sometimes very slight and more than offset by the relatively large increase in the diffusion circles. For example, in Table 3 in 2 and 3 in the second series we find that by using a 1.00 diopter testing cross cylinder we have S.D. = 0.34, which is the difference between diffusion circle diameters of 0.68 and 0.34. By using a 1.50 testing cross cylinder we get S.D. = 0.35, which is the difference between diffusion circle diameters of 0.93 and 0.58. The same spherical difference is more striking when it is the difference between two small diffusion circles than when it is the difference between two large diffusion circles.

The size of the spherical difference, which is the principal element in comparing position (A)

with position (B), depends upon four factors (1) the amount of astigmatism, (2) the strength of the correcting cross cylinder, (3) the obliquity of the correcting cross cylinder, and (4) the strength of the testing cross cylinder. The factor of obliquity is the simplest to note. The greater the obliquity of the correcting cross cylinder, the greater the difference in size between the diffusion circles in positions (A) and (B). But the other three factors are mutually interdependent and do not follow a simple relationship.

Table 4 shows the results of using a fixed combination of a 0.50 D. *correcting* cross cylinder and a 1.00 D. *testing* cross cylinder for determining the axis in different amounts of astigmatism and at different angles of obliquity, and also the results from using a more effective combination. The latter findings constitute the figures in parentheses for S.D. in Table 4. It is evident that the fixed combination is not equally effective, nor generally most effective for the different conditions. However, this combination produces sufficient spherical differences for ready comparison, especially when the angle of obliquity is large, say, 20 degrees, and to a less extent when the angle is 10 degrees. The best combination to be used varies in each case and depends upon various factors.

The power of the testing cross cylinder which is most effective varies with the angle of obliquity, the amount of astigmatism, and the power of the correcting cross cylinder. When the axis is markedly off, say, about 20 degrees or so, the best arrangement generally is a testing cross cylinder which is twice the power of the correcting cross cylinder and is itself equal to the amount of astigmatism; e.g., for an astigmatism of 1.00 D. a correcting cross cylinder of 0.50 D. and a testing cross cylinder of 1.00 D. When the axis is nearly right—that is, to within 10 degrees or, still better, to within 5 degrees, the best arrangement is just the reverse—a testing cross cylinder half the power of the correcting cross cylinder, the latter being equal to the amount of astigmatism—i.e., for an astigmatism of 1.00 D., a correcting cross cylinder of 1.00 and a testing cross cylinder of 0.50. But as one does not know at the beginning of the test what the amount of astigmatism is, unless this has already been determined approximately by other tests, the best procedure is to start with a low power correcting cross cylinder and a higher power, say, twice as strong, testing cross cylinder. Such a combination is a 0.50 D. correcting cross cylinder with a 1.00 D. testing cross cylinder. This will determine the right axis at least very nearly and enough to measure the amount of astigmatism. After the amount has been de-

terminated, a final check on the axis is made by using a testing cross cylinder *half* the strength of the correcting cross cylinder.

After determining the axis, the final step is to determine the amount of astigmatism. Table 5 shows the effect of using 0.25 (± 0.12) testing cross cylinder to determine the correct cylinder power. It is better to think of (A) and (B) now as (A) *plus* cylinder axis 90 and (B) *minus* cylinder axis 90. If (A) is better, more cylinder is required. If (B) is better, less cylinder is required.

Starting with a correcting cross cylinder of 0.25 (± 0.12 C.), we set it at $+0.12$ C. ax. 90 -0.12 C. ax. 180, and apply the testing cross cylinder, say, 0.25 C. (± 0.12 C.), in two positions, (A) $+C$. ax. 90, and (B) $-C$. ax. 90. It is seen from Table 5 that position (A) is better than position (B). A stronger cross cylinder is then inserted, 0.50 C. (± 0.25 C.), and the test repeated. Again (A) is better than (B). So a still stronger cross cylinder is inserted, now 0.75 C. (± 0.37 C.), and the test repeated. Again (A) is preferred, and a 1.00 C. (± 0.50 cyl.) is inserted and the test repeated. Now (A) and (B) give the same results, so the cylinder is right in amount. Suppose we had somehow inserted a cylinder that was too strong, say, 1.25 C. (± 0.62 C.), then, repeating the test, we find now that (B) is better than (A), which shows that less cylinder is required. Fewer changes, of course, are required if the cylinders are changed in larger intervals.

The difference in the size of the diffusion circles between (A) and (B), as long as the cylinder amount is incorrect, equals the strength of the testing cross cylinder, until the residual astigmatism from an undercorrection or an overcorrection is less than the strength of the testing cross cylinder. Then the spherical difference equals the amount of the astigmatism. Thus, if a 0.50 testing cross cylinder is used, the spherical difference is 0.50 until step 4, Table 5, when it is 0.25 because the residual astigmatism now is only 0.25. A stronger testing cross cylinder is therefore preferable, especially in the early stage of the test.

Summary

It is possible to apply cross cylinders for testing and correcting astigmatism in the same way as spherical lenses are used for testing and correcting hyperopia and myopia. The same charts can be used and, what is especially significant, the changes produced in the patient's retinal images are the same as those produced during a test for a spherical error. The procedure is to change the astigmatism to equally mixed astigmatism and maintain it thus throughout the test by the use of *correcting* cross cylinders. In this way, the patient will have to compare images made up of diffusion circles of different sizes, exactly as he does during a test with spherical lenses for a spherical error.

NUTRITION LECTURE

The Mary Swartz Rose Memorial Lecture will be delivered this year by Dr. Henry C. Sherman, of Columbia University. Dr. Sherman, whose subject will be "The Concept and Practical Significance of Internal Environment," will speak at 8:15 P.M.,

February 17, at the Academy of Medicine, 2 East 103 Street. The meeting is sponsored by the Greater New York Dietetic Association, whose purpose in arranging the lecture is to make available information on trends in the field of nutrition.

THE PSYCHIATRIST AND THE BEHAVIOR PROBLEM

ALBERT B. SIEWERS, M.D., Syracuse, New York

THIS communication is a psychiatrist's attempt to formulate an approach to the challenge of the behavior problem child. This report is based upon the writer's experience as psychiatrist to the Department of Education, and to outpatient clinics at the Syracuse Free Dispensary and the Syracuse State Psychopathic Hospital. In all these places cooperation with and by the pediatrician is very close.

The practice of medicine today is no longer concerned solely with the treatment of disease. It is concerned really with the preservation of good health, and health is considered to be not the absence of disease, but a positive sense of well-being. Medicine recognizes in many fields so-called subclinical types in which no actual disease is present, but in which function is disturbed so that radiant health is absent. In like manner, psychiatry is no longer concerned entirely with the treatment of people who are mentally ill. The main purpose of psychiatry has become to furnish for everyone the fullest life possible for that particular individual. The person who is mentally healthy has learned to meet life squarely. He has formed good habits of thinking, reasoning, and concentration; he possesses confidence, self-assurance, and generosity. He has a reasonable understanding and control of his emotions and, all in all, is able to adjust himself to his environment. Psychiatrists do not treat *cases* of dementia praecox, involuntal melancholia, psychoneurosis, or bad children, but, rather, they treat *people* who have dementia praecox, or people who are depressed, people who have neuroses, or children who misbehave. In addition to treatment, there is also definite concern with the prevention of mental illness and the preservation of good health.

For purposes of study, rather than to establish any uniform classification, a psychiatrist who deals largely with children can roughly divide the cases that come to him into three groups:

First, there are those who are born into the world different from the majority of us, as far as physical or mental characteristics are concerned. By far the largest number in this group are those whom we know as backward or defective. These in turn are divided as to educability and trainability. We will take up this point again later on.

Second, there are those who suffer disturbances following diseases, particularly, we might say, encephalitis, poliomyelitis, glandular disturbances, and acute infections.

The third group would be those who are behavior problems, or who show conduct which disturbs parents or teachers so much that they ask for help.

1. Considering the first group, the so-called defectives, the psychiatrist must study the individual as to his educability or trainability, and then study the situation from which the child comes so that all of the resources of the family and of the community can be utilized to help the child. The primary aim is not so much to teach him the "three R's," as it is to teach him how to get along. One of the great difficulties in the regular classroom group is the matter of competition. The defective child, if he is able to compete physically, is unable to do so intellectually or emotionally, and if he is put in the group where he can properly compete intellectually, he outstrips the others physically. Therefore, with the poor emotional development which he has, he soon becomes a behavior problem. Of these we often hear, "He wouldn't do a thing to hurt anybody," but he doesn't know his own strength, and when he plays with smaller children he invariably hurts them.

It is necessary to use the resources of the school system and of the whole community in order to have this child so placed that he will obtain the maximum advantages from all that society has to offer. We do not have to think in terms of placement in an institution so much as we do in terms of educating the family to their particular problem. Often the psychiatrist is called upon to inform parents of children just entering school that they do not belong to the group in which they are placed. It is then that the parents ask why they have not been told before, as the child has been under the care of a pediatrician since birth. It is likely that the pediatrician has been busy checking the physical growth and has either overlooked the mental retardation or has felt that he should be asked about it rather than "stick his neck out" by volunteering information. It seems to me that the training of a pediatrician should include a great deal of consideration of the question of how to approach the parents of such children.

Though the majority of this group are mental defectives, some have other congenital disabilities. Time would not permit separate con-

sideration of the children who are spastic and not defective, or those with choreo-athetosis, or those who are deaf and/or dumb. The principles involved in the management of these cases and their families are, by and large, the same as those that we have already outlined. We probably also should include such conditions as dwarfism or glandular obesity, as here, too, we are concerned with the medical treatment of the patient and the management of the family.

2. Psychiatrists who have seen children of school age unable to do work and who, according to psychologic tests, are subnormal, have been prone to consider that probably these children have always been below normal. We have often glibly said that every such child presents a history of having been dropped by his nurse or having suffered some injury to his head. However, as psychiatrists have learned more, and consequently become more humble, good medical-social histories have shown that a considerable number of these children have had possibly a mild encephalitis, either of the epidemic type or in association with mumps, measles, whooping cough, and the like. I have in mind a boy now 14, who had a psychologic examination at the age of 9, when the quality of his work first began to fall off. On account of changes in schools and changes in teachers, additional psychologic tests have since been given with each change in the school term. According to the original test, this boy had an I.Q. of 100; six months later it was 98; next term it was 95; and so on, until, according to our tests, he has an I.Q. of about 75 at the present time. It can readily be seen that this boy had not increased his capacity to learn since he was 9 years old. At first glance, there was nothing unusual in his history. He came from a rather large family and had the usual childhood diseases. A more searching history, however, revealed that when the boy had mumps at about the age of 9 he "had it different and harder than the other children in the family and in the neighborhood." Further study revealed a few vague neurologic signs and also some glandular disturbances similar to pituitary dwarfism. Under medical treatment for post-encephalitis, this boy's behavior improved, and he is beginning to make a much better emotional adjustment. There has, however, been no change in his apparent capacity to learn.

3. Our next group, which also includes the behavior problems, encompasses the psychoneuroses and the so-called borderline psychosomatic cases. This group is very large and calls for a consideration of the general approach as well as for illustration by particular cases. Phobias and obsessions might outwardly seem a far cry from stealing and truancy, or from bladder and intes-

tinal upsets, yet all these and many more have been attributed to a common cause. This common cause is not a pin-point sort of thing, but rather a broad base variously spoken of as (1) the evasion of reality, (2) anxiety, or (3) insecurity. Whatever the organ or function fixed upon, the symptoms or behavior are likely to be accompanied by anxiety. We all know the symptoms of acute anxiety. We have all felt a quickening of the pulse and increased respiration when called upon to handle an emergency. These signs might be momentarily distressing, but they really indicate better preparation on the part of nature for doing the particular job. It is only when this anxiety becomes chronic or so marked that a paralysis of action or other panic results that we become concerned. *A good many parents themselves have a sort of chronic anxiety*, and this may be reflected in the child as insecurity, showing through the medium of behavior or disease symptoms. These symptoms are often severe enough to make one suspect organic disease or at least to conduct sufficient medical examination to rule out its presence. It therefore becomes apparent that treatment must be directed at the force behind the production of the symptoms or behavior. The child's fears of insecurity must be relieved, and one of the big factors in this is education of the parents. Now, let us assume that the child has a stomach-ache, and that careful study by a pediatrician reveals no organic basis for this but, instead, shows an emotional one. Is it quite fair to let the child and his parents believe that it is just his stomach that is misbehaving? This is really a reaction of the total personality. If we think no further than the stomach-ache, then maybe it is all right to give a bitter tonic or even some nauseating dose to discourage the stomach's misbehavior. I feel, though, that if we are to treat such a condition rationally it would involve a thorough knowledge of the background of the child and the development of the symptom and that the treatment should be directed at the adjustment of the whole individual, not just to his stomach.

A child who had attended a party the evening before became sick on his way to school the following morning. It so happened that by returning home and staying there that day he missed a quiz. The next time a quiz was to be held the same thing happened. In the first instance, the mother treated the child herself. The second time she called the doctor, who attempted to assure her that it was nothing to be concerned about. When, however, it happened a third time, the result was an illustration of the old saw that bad patients make bad doctors. The mother, in her anxiety, pestered the physician. She was fearful that Johnny would grow up to be like the

rest of the Joneses and have a weak stomach. The doctor had no further treatment to suggest, and when the mother insisted on an x-ray, he arranged for such an examination. This did not have the salubrious result that was expected, but tended, in spite of the reports, to fix in the mother's mind the idea that the child was to go through life with a weak stomach.

In this particular case, the child proved easier to deal with than did the mother. In direct contact with the psychiatrist, the child began to "open up," and the trend of his talk showed that his mother's anxiety bothered him considerably. When the mother insisted upon seeing the psychiatrist after the interview, the boy became anxious lest the psychiatrist expose him. Subsequent interviews were so arranged that the boy could be assured that this would not happen. In fact, the mother was not allowed in the office at all, but was seen at an entirely separate time. It was not long before the boy expressed his interpretation of the situation in about this manner: "I guess it's the devil or something always inside of me that makes this thing happen. I'd like to get rid of it. Mama still has hers because she's always doing the things like I have done." The mother was helped, at least to the point where she no longer continually suggested that the boy was ill. (He was an only child and the mother was really expending all her emotion on him.) Further back in this picture was a maladjustment between the mother and father which, as a result of these interviews, began to clear up. The security of the whole family was improved. These parents were cooperative and intelligent, and they were able, with such help as was given them, to make changes in their adjustments to each other and to their own families so that treatment really extended into the third generation.

In the matter of behavior problems, simple attention-getting behavior is often overcome by pointing out to the parents the need of the child for attention and having them give attention to the desirable things he does. This gives him a feeling of security and leads to better behavior. All of us know the importance of having a definite objective when we do feel anxiety, and the same plan may be applied within the family where there is anxiety and attention-getting behavior. The mother can be shown the value of having definite tasks for the child. In these days this requires a little more *ingenuity than formerly*, but hardly any child able to run around is incapable of learning to put away his own toys and clothes. Tasks, of course, should be assigned as a part of a cooperative procedure. Endeavors in this direction are doomed to failure if the mother tries to use a task as a reward or as praise for the

child one day and as punishment another.

Rules will never take the place of thinking, and the psychiatrist must be a detective who traces down contributing factors and finds out how they can be modified. This results in the development of a plan, vague at first, but more definite as the study goes on. We cannot afford to overlook any detail, and I cannot stress too strongly the need of a very comprehensive medical-social history. It is almost impossible to do this work single-handed. The psychiatric social worker occupies a key position, as does the pediatrician. In fact, there is no reason why the pediatrician could not also be the psychiatrist. And as an arsenal we have the resources of the family, the school, and the community. The psychiatrist, I think, is the logical one to coordinate these forces.

In 88 reporting juvenile courts of the United States 21,000 children were seen for stealing during 1930. We realize that there are innumerable petty thefts in the home, in the school, and in the neighborhood that are not reported to anyone. Therefore, it can be said that stealing is not an uncommon behavior problem, but many of these thefts are based simply upon the desire for possession, and maybe should not even be called stealing. There are, however, cases of stealing which definitely belong to the classification of kleptomania, and these are recognized by the fact that even if the stealing is left out of the picture there are still other personality difficulties. The child, himself, with encouragement in a psychiatric interview, will often analyze his own stealing in such a way as to remove the factors that lead up to it.

I should like to mention two cases of stealing that were acute and which were attended by other personality difficulties. Another reason for mentioning them is that they cleared up so quickly. One was in a girl who was adopted and whose parents attempted to deceive her about this. The child found out from other sources, and then trouble began. A frank explanation of the state of affairs seemed all that was needed. The other girl stole and associated with undesirable companions. It turned out that these undesirable companions were the only other girls she knew who had no allowance. The mother, who was a most distrusting person, got most of the attention, and the problem promptly cleared up.

Summary

In this presentation we have emphasized that the aim of psychiatry is the fullest life possible for each individual. We have considered those who are handicapped congenitally, those who suffered handicaps as a result of intercurrent disease, and the psychosomatic, psychoneurotic, and behavior problem child. The indicated

treatment is to learn as much as possible about the whole situation, rather than about the single individual. Treatment is directed at modifying the whole situation, and the individual is considered as a sick personality rather than one who has a part of him sick. We cannot be content with saying that a person has a sick stomach. If he does have, we must realize that he is sick all over. In like manner, sick individuals mean sick families. Deception and surprise as methods of treatment are useful only as symptomatic treatment and are usually used because of ignorance of the fact that only a symptom is being dealt with or because we lack facilities for knowing and modifying the whole situation.

Discussion

Dr. T. W. Brockbank, *New York City*—Dr. Siewers' paper has covered many aspects of his topic in a concentrated manner and in all too short a time to do the subject full justice. In the short time at his disposal he has not been able to go deeply into the emotional ramifications often found in behavior problems, nor does this seem to be necessary for the purpose of the paper. We may not be inclined to concur with his working classification of behavior problems, but such a classification does serve the purpose of simplifying his presentation.

Our clinic work with children over the past ten or fifteen years has provided a humbling influence for most psychiatrists engaged in this field. We have found that the social worker has a lot to contribute to our studies and also that the contribution of the psychologist is practically indispensable. Dr. Siewers has not emphasized this latter point as much as I feel it deserves.

Another point, I believe, should be clarified. I am sure Dr. Siewers did not wish to convey the impression that the pediatrician without psychiatric training could or should take care of the behavior problems of children. Today the diagnosis and therapy of such problems should be in the hands of the psychiatrist. We have found that the roots of behavior problems run deep, not only in the child himself but also in those close to him, and they cannot be eradicated by a placebo or some local organic therapy.

I should like to endorse Dr. Siewers' successful handling of the child in his environmental setting as distinct from that approach which attempts to treat the child alone.

There are divergencies of opinion concerning the proper therapeutic methods to employ in the handling of the uncomplicated behavior problem—Dr. Siewers' group 3. I quite agree with him that the environment of the child should be tapped, sounded, and worked with if we wish to carry out a practical job with most of these children. Excluding a research approach, I think it is asking too much of psychiatry to deal with the child alone in the direct treatment, to the exclusion of all other approaches. Even the most rabid and radical psychotherapists admit this when they select their cases for treatment.

The careful selection of cases is done in many clinics in order chiefly to pick out those who will respond to direct psychotherapy. If we are willing to work with the parents, as well as with other environmental factors of many of those children who are rejected for direct psychotherapy, we will find that they, too, will respond to our efforts although the approach is not a purely psychiatric one.

In conclusion, Dr. Siewers' paper is a good practical contribution to the discussion of the handling of the behavior problem in children.

MEDICAL EDUCATION CONGRESS DATES

The Thirty-Ninth Annual Congress on Medical Education and Licensure, sponsored by the Council on Medical Education and Licensure of the American Medical Association, will be held at the Palmer House, Chicago, February 15 and 16, the *J.A.M.A.* announces in its January 23 issue. The Federation of State Medical Boards of the United States will participate in the congress. Discussing problems to be brought before the congress, the *Journal* reports:

"The mobilization of the medical profession for service to the armed forces and to civilians and the maintenance of production of physicians have been fraught with many difficulties. The medical schools of the country have voluntarily reduced the period required for the curriculum of the medical school from four to three years. The required pre-medical college course has been reduced to two academic years. Now the War Manpower Commission and other federal agencies have formulated a coordinated program looking to the satisfactory

training of an adequate number of physicians to meet both the military and the civilian needs The seriousness of the many problems involved . . . emphasizes the importance of the Annual Congress on Medical Education and Licensure. . . . One of the greatest problems involved in the mobilization of the medical profession is the meeting of changing civilian and industrial needs. This calls for the relocation of many physicians and the consequent adjustment of state licensure regulations. The program, including as it does addresses by President Elliott, chief of the Professional and Technical Employment and Training Division of the War Manpower Commission, General Dalton, of the U.S. Army, representatives of the Office of Procurement and Assignment and the Surgeon Generals of the U.S. Army, the U.S. Navy, and the U.S. Public Health Service, should go far toward clarifying the details of the various programs involving the whole field of medicine in the war."—*A.M.A. News*, January 21

OSTEOID-OSTEOMA

Report of Five Cases

SAMUEL KLEINBERG, M.D., New York City

OSTEOID-osteoma, although relatively frequent in occurrence, is not generally well known. Its easy surgical removal from most locations where it is found and the invariable postoperative cure probably account for the fact that, although many cases have undoubtedly been operated upon in the past, there has not been an adequate interest in the exact nature of this bone lesion. It has undoubtedly often been mistaken for either a nonsuppurative sclerosing osteomyelitis, so-called Garre's disease, or an isolated bone abscess—that is, a Brodie's abscess without frank pus formation. In recent years Jaffe^{1,2,3} and his associates at the Hospital for Joint Diseases have studied this subject and convinced themselves and many others that the lesion is a special pathologic entity having no relation to an inflammatory or suppurative process. Jaffe has very thoroughly reviewed the clinical picture and has described in detail the gross and microscopic pathology. This lesion, which he has named osteoid-osteoma, has a rather typical clinical course, a characteristic roentgenographic appearance, and a pathognomonic histopathology which, when once appreciated, render the diagnosis relatively simple.

An osteoid-osteoma is a small lesion, rarely larger than a ten-cent piece, located in cancellous or cortical bone but sometimes also under the periosteum. It represents a displacement of normal bone tissue by osteoid and calcified vascular connective tissue surrounded by a variable zone of sclerosis with or without periosteal new bone formation. In some instances the lesion may become so densely ossified that it is difficult to distinguish it from the adjacent bone. The name "osteoid-osteoma" indicates the essential pathologic change, namely, a benign nonmetastasizing tumor which in its earliest stages consists of osteoid tissue and later becomes hypercalcified and ossified.

The distinguishing features of an osteoid-osteoma may be summarized as follows: The disease occurs chiefly in the second and third decades of life but may be found in infants and in older people. The onset is always insidious and is seemingly unrelated to injury, infection, or, so far as is known now, to any other causative agent. Pain is the outstanding symptom. It is definitely localized or at least most marked

at the area of the disease, although there may be some radiation. Mild and intermittent at first, it gradually increases in intensity until finally it becomes continuous and disabling. Exceptionally the pain may remain mild, as it did for two years in a case which I previously reported.*

Tenderness to pressure is constant and clinically is second in importance only to the pain. It is located at the site of the disease and can be readily elicited by a careful examination. It is naturally most marked in superficial lesions, but it can be obtained even in such regions as the upper end of the femur where pressure must be applied through a thick musculature. Theoretically, it might not be obtainable if the lesion is in the body of a vertebra. In infants, as in Case 5 of the present series, the localization of the area of greatest tenderness is an excellent guide to the exact site of the tumor. The clinical triad of an insidious but continuing discomfort, localized pain, and localized tenderness should lead us to at least suspect an osteoid-osteoma.

Roentgenographically the lesion appears as a small area of rarefaction surrounded by a zone of bone sclerosis. The bone sclerosis may be little more than a narrow ring or, when located in a shaft cortex, may extend to several inches on either side of the central focus and may be one or two inches in thickness. In the late stages of the process the lesion may be very dense, denser than the surrounding bone. It is, however, recognizable because of a narrow radiolucent ring between the central nidus and the reactive perifocal osteosclerosis. The lesion is circumscribed, never appears invasive, as other bone tumors so often do, and never metastasizes.

Histologically there are specific pathognomonic changes. There is a central focus of osteoid tissue in various stages of calcification and ossification lying in a substratum of vascular connective tissue and surrounded by dense trabeculae of bone.

Surgically osteoid-osteoma is a very satisfactory disease to manage, for when the excision is complete the symptoms disappear, and they have not recurred in any of the known cases. Because of the small size of the lesion one must be certain at operation that it is completely removed; otherwise the symptoms will continue. Thus it is imperative that during the operation one have the opportunity of x-raying the field

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1942.

* Am. J. Surg. 53: 1 (July) 1941.

for both accurate localization of the osteoid-osteoma and postoperative assurance that the tumor has been extirpated. The removal of all or even a large part of the reactionary sclerosed bone does not seem necessary so long as the primary focus is excised.

Our ignorance of the cause and origin of osteoid-osteoma is the most cogent reason for reporting some additional cases, in the hope that as our knowledge of this disease increases someone will be able to explain its pathogenesis. The present report is further prompted by the fact that additional experience has shown that the lesion occurs over a wider age range than previously recorded cases indicated. In Dr. Jaffe's group of 33 patients, the youngest was 4 years old and the oldest was 33, while the youngest in my present series is 1½ years old and the oldest is 45. Moreover, in 2 of my cases the lesion was near the lesser trochanter, the operative approach to which is difficult, and I desire to emphasize the fact that the complete removal of the tumor from this site requires the assistance of roentgenography during the operation for its accurate localization. In fact, in all operations on osteoid-osteoma one should not close the wound without a check-up x-ray film showing that the tumor area has been completely excised.

Case Reports

Case 1.—Mrs. E. R., 45 years old, was referred to me by Dr. Alfred Pollak for continuous pain in the left knee of two years' duration. The onset of the pain was insidious without any known antecedent injury or illness. The pain was at first mild and intermittent but soon became continuous, severe, and disabling. Numerous x-ray films were interpreted as showing arthritic changes but these were hardly extensive enough to account for the severe pain. The patient continued to suffer, could not sleep, and was becoming increasingly distracted and weakened. In this state of discouragement she consulted me on November 11, 1940, complaining of pain in the left knee, and significantly pointing to one spot on the antero-external surface of the knee as the location of her great discomfort.

Examination: The patient walked with a limp on the left side and, although the left knee appeared normal, there was a one-inch atrophy of the left calf. The joint was freely movable and there was no local heat or excessive joint fluid. At the site of her pain there was exquisite tenderness to pressure limited to an area of about ½ inch square. Away from this region there was no tenderness. The tender spot was located over the articular surface of the external femoral condyle at the junction of the anterior and lateral surfaces. An x-ray film (Fig. 1) made on September 14, 1940, showed a lesion in the lateral femoral condyle at the exact site of the pain and tenderness. There was seen a small irregularly oval area of bone, about ¼ inch in diameter, surrounded by a narrow zone of rarefaction lying in the

FIG. 1. Case 1. Antero-posterior view of the knee showing the lesion in the outer condyle of the femur. Note the circular area of bone surrounded by a radiolucent zone in a patch of porotic bone.

midst of a larger irregular patch of porotic bone. The central piece of bone looked like a sequestrum except that its density was not as pronounced as that of dead bone.

This lesion was visible in several but not in all of the many roentgenograms which had been taken prior to and after September, 1940, and, because of its inconspicuousness, it might readily be overlooked. Incidentally, no such structural pathology was seen in any of the films of the right knee. A diagnosis of osteoid-osteoma was made, and, on the basis of the prolonged illness, the localized pain and tenderness, and the roentgenographic appearance, an operation was advised.

The operation was performed on November 14, 1940, under spinal anesthesia. The knee was flexed to a right angle over the edge of the table and a 3-inch vertical incision was made lateral to the patella. Upon incision and retraction of the joint capsule there immediately came into view an indented area on the articular surface of the lateral femoral condyle near its outer border. The involved area measured about ½ by ⅜ inch and affected both the anterior and the lateral aspects of the condyle. In the center of the depression was an area of bluish discoloration. The articular cartilage immediately surrounding the bluish area appeared gray and thin; the adjacent articular cartilage had a normal grayish, glistening appearance. With an osteotome the diseased mass was removed to a depth of ½ inch, exposing normal cancellous bone, neither unduly vascular nor sclerotic. The rest of the knee joint appeared normal. The wound was closed in layers and healed by primary union. The patient was promptly relieved of her pain, which has not recurred.

FIG. 2. Case 1. Cross section, low magnification ($\times 6$). Note differentiation between central osteoid tissue (A) and normal cancellous bone at periphery (B).

FIG. 3. Case 1. High-power magnification ($\times 150$) of the central nidus shows markedly calcified and osteoid tissue.

A cross section of the specimen (Fig. 2) shows the typical appearance of this lesion. There is a central circular nidus (A) of osteoid tissue surrounded by normal cancellous bone (B). A high-power magnification (Fig. 3) of the central nidus shows markedly calcified and osteoid tissue. Twenty-eight sections were made in various planes of this specimen, and in not a single one of these was there any evidence of inflammation.

Case 2.—Simon S., 29 years old, was referred to me by Dr. R. Goldenberg on March 3, 1941, with a diagnosis of osteoid-osteoma. His chief complaint was sharp recurrent pain in the upper part of the front of the right thigh and an occasional limp after considerable walking. The pain had appeared insidiously about six months previously without any known antecedent illness or injury. It recurred intermittently, varied in intensity, came on in spells during the day or at night, and in the last few months had been increasing in degree.

The patient was a well-built, muscular, robust individual who seemed in excellent health. The physical examination revealed no abnormality except for mild tenderness to pressure over the front of the thigh at the level of the lesser trochanter. The motions in the right hip were free and painless. The roentgenogram (Fig. 4) revealed a lesion in the

intertrochanteric area of the femur nearer the lesser than the greater trochanter. The lesion appeared as a circular area of rarefaction about $\frac{1}{2}$ inch in diameter, within which there were spots of increased calcification. The surrounding bone was normal. The clinical diagnosis of osteoid-osteoma was confirmed and an operation advised.

Operation: The patient was operated upon on March 22, 1941. The femur was exposed through a vertical anterior incision. By a check-up x-ray film with an artery clamp at the approximate site of the osteoid-osteoma its exact location was identified and assured. A square of cortical bone was removed, revealing an oval mass of softened bone in a shell of harder bone. The softened mass shelled out like a kernel. The pathologic examination (Fig 5) showed, as in the previous case, the typical findings of an osteoid-osteoma confirming the original diagnosis.

Case 3.—Robert L., 17 years old, was referred to my clinic in October, 1939, for a lump on the right side, which he had just noticed six months before. Several months previously he had had an infection of the upper respiratory tract, which continued intermittently until about the time when he was observed to limp. In July, 1939, the boy first experienced pain along the upper part of the inner side of

FIG. 4. Case 2. Antero-posterior view showing a circular area of rarefaction along the intertrochanteric line only faintly differentiated from surrounding bone. There is almost no reactionary sclerosis of bone.

the right thigh. The pain was rather annoying at night and often disturbed his sleep. A marked atrophy of the right thigh had been noticed as early as April, 1939.

The examination showed a tall, muscular boy who walked awkwardly rather than with a limp. There was tenderness to pressure over the front of the thigh near the lesser trochanter. The motions in the right hip were normal, but at the extreme of abduction he had pain in the upper part of the thigh. The roentgenograms showed a marked widening and thickening of the femur just below the intertrochanteric line for a distance of about 3 inches. Lateral to the lesser trochanter was discernible an area of rarefaction about as big as a dime, seen more clearly in the lateral (Fig. 6) than in the antero-posterior view. Within this porotic zone was a mass of irregularly thickened bone. There was a very extensive osteoperiosteal thickening of the femur along the inner surface for about an inch above and 3 inches below the lesser trochanter.

This patient was operated on in October, 1939, through a vertical incision on the front of the upper part of the thigh. I had felt that by exposing the front of the femur and identifying the greater and lesser trochanters I should have no difficulty in finding and excising the lesion. At the operation, on removing a square of the cortical bone I thought I located some softened tissue which must be the osteoid-osteoma. I excised this and closed the wound. The patient was not relieved. The microscopic examination of the removed tissue showed that it was not the osteoid-osteoma, and new x-ray films exhibited the lesion to be a little to the inner side of the area operated upon. I therefore urged a second

FIG. 5. Case 2. Photomicrograph ($\times 12$) of a section through the lesion represented by the rarefied area in Fig. 4. This osteoid-osteoma is composed in part by large sheets of calcifying and ossifying osteoid (A). At B is seen hypercalcified trabeculae of new bone, and at C vascular connective tissue.

FIG. 6. Case 3. Lateral x-ray film showing the lesion very clearly. Note the extensive reactionary new bone.

operation, which I performed in December, 1940. This time I made sure of the exact location of the lesion by placing an instrument at its approximate site and having an x-ray film made before I excised

FIG. 2. Case 1. Cross section, low magnification ($\times 6$). Note differentiation between central osteoid tissue (A) and normal cancellous bone at periphery (B).

FIG. 3. Case 1. High-power magnification ($\times 150$) of the central nidus shows markedly calcified and osteoid tissue.

A cross section of the specimen (Fig. 2) shows the typical appearance of this lesion. There is a central circular nidus (A) of osteoid tissue surrounded by normal cancellous bone (B). A high-power magnification (Fig. 3) of the central nidus shows markedly calcified and osteoid tissue. Twenty-eight sections were made in various planes of this specimen, and in not a single one of these was there any evidence of inflammation.

Case 2.—Simon S., 29 years old, was referred to me by Dr. R. Goldenberg on March 3, 1941, with a diagnosis of osteoid-osteoma. His chief complaint was sharp recurrent pain in the upper part of the front of the right thigh and an occasional limp after considerable walking. The pain had appeared insidiously about six months previously without any known antecedent illness or injury. It recurred intermittently, varied in intensity, came on in spells during the day or at night, and in the last few months had been increasing in degree.

The patient was a well-built, muscular, robust individual who seemed in excellent health. The physical examination revealed no abnormality except for mild tenderness to pressure over the front of the thigh at the level of the lesser trochanter. The motions in the right hip were free and painless. The roentgenogram (Fig. 4) revealed a lesion in the

intertrochanteric area of the femur nearer the lesser than the greater trochanter. The lesion appeared as a circular area of rarefaction about $\frac{1}{2}$ inch in diameter, within which there were spots of increased calcification. The surrounding bone was normal. The clinical diagnosis of osteoid-osteoma was confirmed and an operation advised.

Operation: The patient was operated upon on March 22, 1941. The femur was exposed through a vertical anterior incision. By a check-up x-ray film with an artery clamp at the approximate site of the osteoid-osteoma its exact location was identified and assured. A square of cortical bone was removed, revealing an oval mass of softened bone in a shell of harder bone. The softened mass shelled out like a kernel. The pathologic examination (Fig 5) showed, as in the previous case, the typical findings of an osteoid-osteoma confirming the original diagnosis.

Case 3.—Robert L., 17 years old, was referred to my clinic in October, 1939, for a limp on the right side, which he had just noticed six months before. Several months previously he had had an infection of the upper respiratory tract, which continued intermittently until about the time when he was observed to limp. In July, 1939, the boy first experienced pain along the upper part of the inner side of

FIG. 9. Case 5. The antero-posterior roentgenogram showed a diffuse enlargement and marked sclerosis of the upper two-fifths of the shaft of the tibia. The osteosclerosis involved the inner part of the shaft to a greater degree than the outer surface. This lateral view presents an anterior bowing and marked thickening of the upper part of the shaft and a large area of intramedullary bone sclerosis that resembles a sequestrum.

The patient presented a marked knock-knee deformity on the right side, with a conspicuous prominence and enlargement of the upper portion of the tibia. The circumference of the right leg near the knee was $\frac{3}{8}$ of an inch larger than that of the corresponding portion of the left leg. There was exquisite tenderness to pressure over the upper part of the right tibia, but no tenderness elsewhere in the right leg or in any part of the left leg. The roentgenograms showed extensive changes in the right tibia. In the antero-posterior film one saw a diffuse enlargement and sclerosis of the upper two-fifths of the tibia, the sclerosis involving the inner side mainly, and the outer side only slightly. The lateral view (Fig. 9) showed an extensive linear thickening

FIG. 10. Case 5. In the high-power ($\times 250$) magnification note active reconstruction, vascularization, and new bone deposition about the vessel spaces in the nidus. Much of the interstitial osseous tissue of the nidus shows poor staining or absence of staining of its nuclei, notably in the areas marked *a*.

of the anterior cortex and a large sequestrum in the marrow cavity, with moderate sclerosis of the posterior surface of the tibia. The central elongated sclerotic mass or sequestrum was completely surrounded by a zone of translucent or normal-appearing medullary or cancellous bone. The tibia was bowed forward considerably at the level of the lesion.

We were very much puzzled as to what this lesion in an infant $1\frac{1}{2}$ years old might be. The child was not ill enough for a pyogenic osteomyelitis. Moreover, there was no history of any sudden onset with fever, malaise, and toxicity, which regularly accompany an acute hematogenous osteomyelitis, especially in a baby. A blood count was normal and the Wassermann and Kahn tests were negative. The roentgenologist's report was "an osteoperiostitis of the tibia, the character of which was not radiographically evident." The child was observed for six weeks, during which period his temperature remained normal and he otherwise behaved normally except for the persistence of the deformity, the tenderness of the right leg, and the awkward gait.

He was operated upon on March 3, 1942. A complete saucerization of the upper end of the tibia was done under tourniquet control. The periosteum of the tibia was markedly thickened. The bulging mass of the tibial cortex was removed in one block. Underlying this was spongy bone in which was embedded a whitish eburnated bony mass 1 inch long and $\frac{1}{2}$ inch wide. This eburnated bone was completely removed. The floor of the cavity was thoroughly curetted. There was no pus and no walled-off abscess anywhere in the wound. The wound was closed without drainage and is healing by primary union.

The microscopic study of the intramedullary, sequestrum-like, bony mass showed it to be most likely an osteoid-osteoma (Fig. 10). A low-power

FIG. 7. Case 3. Photomicrograph ($\times 12$) of a section through the lesion represented by the rarefied nidus in the thickened femoral cortex shown in Fig. 6. (A) Calcifying osteoid. (B) Ossifying osteoid. (C) Connective tissue substructure. (D) Blood vessel space.

any bone. The osteoid-osteoma was located and removed. It appeared as a kernel of softened bone within a shell of harder bone. After this operation the boy was promptly relieved of all pain and has remained well.

The microscopic examination (Fig. 7) of the osteoid-osteoma showed the characteristic pathognomonic findings of a central focus of calcifying and ossifying osteoid tissue surrounded by an extensive osteosclerosis.

Case 4.—P.C., an 11-year-old girl, was referred to me by Dr. Langsam for swelling of the left ankle which had first been noticed a few weeks previously. The child had occasional pains in the leg, extending up to the knee. She appeared in good general condition and walked without a limp, although I was told that at times she did limp. The subjective symptoms were very mild. The left leg presented a very definite swelling, occupying its lower one-fourth. The swelling was most marked on the inner side where there was an elevation of the surface temperature and exquisite tenderness to pressure at a point about 3 inches above the tip of the internal malleolus. The x-ray films (Fig. 8) showed an extensive enlargement and sclerosis of the lower 3 inches of the tibial diaphysis, and in the center of the sclerotic bone a small oval area of rarefaction a little more than $1\frac{1}{2}$ inch in diameter. The diagnoses considered were chronic osteomyelitis with a central and deep-seated abscess, a sclerosing nonsuppurating osteomyelitis, a Brodie's abscess, and an osteoid-osteoma.

At operation, performed on January 9, 1942, the bone was found to be exceedingly dense and greatly enlarged. There was no abscess, but at the level of the rarefied area was found a small nidus of softened tissue within the cortex of the tibia. A very thorough saucerization was done and the wound

FIG. 8. Case 4. Marked enlargement and sclerosis of the lower fourth of the tibia with a small oval area of rarefaction in the cortex about 3 inches above the malleolus.

was closed without drainage. The wound healed by primary union and the patient has been completely relieved. The pathologic examination showed an osteoid-osteoma with the typical morphologic changes.

Case 5.—This is probably the most interesting of all my cases. From the diagnostic point of view it was the most difficult because of the age of the patient and the peculiar x-ray appearance. The patient, J. W., a boy $1\frac{1}{2}$ years old, was brought to me on January 19, 1942, because he walked awkwardly and constantly turned his right leg outward. He had begun to walk two and one-half months previously. The awkward gait had been noticed promptly. It was supposed to be due to an inequality in the length of the legs, for which a compensating lift in one shoe was prescribed. The child had had no injuries and no spells of fever. He was playful and seemingly had no pain, at least none that prevented walking.

HISTAMINASE INTRAMUSCULARLY IN HAY FEVER

D. EDWARD FRANK, M.D., New York City

MUCH has been written about the relationship of histamine to allergic phenomena ever since Dale and Laidlaw,¹ in 1910, pointed out the similarities between anaphylaxis and histamine shock. Many allergists are convinced that allergic disorders are due to the release of either histamine or a histamine-like substance in the affected tissues. Within the past few years much clinical evidence has been submitted²⁻⁷ purporting to show that histaminase, an enzyme extracted from the kidneys and intestinal mucosa of hogs, effectively aids a goodly percentage of allergic disorders. The explanation for such beneficial results has been based on the theory that histaminase, which is capable of inactivating histamine *in vitro*, probably acts similarly *in vivo*. However, very little experimental work has been reported substantiating the latter supposition. The work of Karady and Browne,⁸ which reported protection against anaphylactic shock in guinea pigs by injection of histaminase fifteen minutes before the shock dose of antigen, has not been confirmed by the author.⁹ Barlow and Homburger¹⁰ reported similar protection against anaphylactic shock when the histaminase was given as a series of injections for several days preceding the shock dose. The author⁹ was able to confirm that histaminase given in such a manner offered some measure of protection against anaphylaxis in guinea pigs. For this reason, it was felt histaminase deserved a clinical trial. Harris and Frank⁹ have already reported the failure of histaminase, given orally, to protect against asthma. But since experimental results were obtained with parenteral injections, we decided to try histaminase, intramuscularly. The present article reports its use, intramuscularly, in seasonal ragweed pollinosis.

During the past two years we have treated 101 cases of hay fever with histaminase, intramuscularly, seeing 16 cases in 1940 and 85 cases in 1941. In 1940, assuming the histamine inactivation theory as a basis for operation, we treated cases, coseasonally, because we assumed that during the season, when the patient was suffering, the maximum amount of histamine should be released in the tissues. Unfortunately, only 9 cases presented themselves during the latter part of August for coseasonal treatment. Of these, 6 cases were benefited but only 3 obtained very satisfactory results. These results are too

meager, statistically, to be more than mentioned before we pass on to the 1941 season.

In 1941 we treated 85 ragweed pollinosis cases divided into three main groups: a pre-seasonal group, a pre- and coseasonal group, and a coseasonal group. We were able to check results properly in but 69 of the cases. Of the 69 cases treated, 44 had had pollen therapy in previous seasons. Twenty-five did not have previous pollen therapy. The patients, in the month of July, received one injection weekly of 4 units of histaminase. (We found the 4 unit ampules less toxic than those used in 1940. The reactions resulting were strictly limited to a development of local pain 3 or 4 hours after the injection, lasting from several to forty-eight hours. After a few injections, usually little or no pain was felt.)

In the month of August, patients received every week two injections of 4 to 6 units each, until about August 20. At that time, in some patients who began to manifest hay fever symptoms the dosage was raised to 9 or 12 units every other day. In coseasonal cases appearing after August 20, injections of from 6 to 12 units were given daily or every other day.

The total number of injections, the frequency of them, and the total unitage received varied with the date the patient started treatment and with his ability to cooperate and to stand the pain of repeated injections. Eighty per cent of the patients were given between 25 and 50 total units of histaminase; 90 per cent received between five and ten injections.

Analysis of results from the point of view of the total number of injections received showed only slight variations between those receiving from one to five and those receiving from five to ten, or over ten injections. Equally, there was insignificant variation in the results obtained with patients receiving 4 to 25 units and those receiving 25 to 50 units or over 50 units.

Table I presents the results obtained in the present study. The column "Better than Last Year" does not necessarily indicate an excellent result. It merely indicates that the thing the patient recalls most about his hay fever—how he felt last year—has been chosen as a basis for comparison. If the patient had had no previous therapy, the results under histaminase were contrasted with his usual symptoms without therapy. On the other hand, if he had had pollen therapy last year, results were contrasted with those under pollen therapy. This occurred in 44

($\times 10$) photomicrograph showed a section of the sclerotic nidus surrounded by compact bone of normal structure. In the high power ($\times 250$) photomicrograph (seen in Fig. 10) we note active reconstruction, vascularization, and new bone deposition about the vessel spaces in the nidus. Much of the interstitial osseous tissue of the nidus (i.e., the bone between the areas of new bone) shows poor straining or absence of staining of its nuclei. There is no evidence of inflammation anywhere in the nidus, nor were there evidences of inflammation in many additional blocks of tissue examined from this case.

Summary

There are here recorded five additional cases of osteoid-osteoma in patients varying in age from $1\frac{1}{2}$ years to 45 years. From this experience we must appreciate the fact that this tumor may occur at practically any age, though the majority of the patients are in the second and third decades of life. The history in all of these patients was similar to that obtained in all previous cases, and showed that the tumor appears insidiously and that its symptoms, particularly

pain, are at first vague and mild. After several months, however, the pain becomes persistent, increasingly severe, and disabling. In children the disability may be the first and the most conspicuous symptom. Tenderness is the most important objective sign, since it is always present and establishes the location of the pathology, which is usually very clearly visualized in the roentgenograms. In osteoid-osteoma, as in most osseous lesions, x-ray films should be made in several planes since only some of the views may reveal the changed morphology. Histologically the lesion is a benign tumor consisting of a central nidus of osteoid tissue in various stages of calcification and ossification, surrounded by a variable zone of osteosclerosis. The only effective treatment is thorough surgical removal of the tumor.

FIFTEEN-YEAR STUDY OF RHEUMATIC HEART DISEASE

When rheumatic heart disease begins in childhood, 69 per cent survive childhood, 35 per cent survive adolescence, 18 per cent reach the age of 30, and 5 per cent live beyond the age of 45. Alfred E. Cohn, M.D., and Claire Lingg, of New York City, report in the *J.A.M.A.* for January 2. "When the disease begins in adolescence," they say, "85 per cent survive this age period, 55 per cent reach the age of 30, and 21 per cent the age of 46 or more. When the onset is in the twenties, 23 per cent, and when it is after 30, 44 per cent survive the age of 45."

These findings are based on a study which occupied the authors continuously for fifteen years, during which 3,129 patients with rheumatic heart disease were observed until death.

"The supposition is general that girls are more often afflicted than boys," the authors say, "but when so large an experience as this is available it appears that this is not the case—the two sexes are afflicted in equal numbers. There were 1,566 males and 1,563 females."

Among the other important facts about the disease revealed by this study is that there is no important difference between the sexes in the age at onset. The mean age for males is about 14 years and for females about 15 years.

"Rheumatic fever," the authors say, "may begin at any age, but it usually begins in childhood, especially between the ages of 5 and 10 years. At 15, 70 per cent of persons afflicted have already acquired the disease."

"In youth, the onset of the disease is characterized by polyarthritis in about half and by carditis or chorea in about one-third. In adult life, the onset is characterized chiefly by polyarthritis and, with advancing age, by the appearance of valvular lesions alone."

"The mean duration of the disease is about thirteen years; 50 per cent of patients die within nine years after onset, but 25 per cent live more than seventeen years and 10 per cent for thirty or more years. . . ."

"Of all cases of rheumatic cardiac disease, 65 per cent are to be found in childhood. In the remaining 35 per cent the disease is acquired at later age periods. In adolescence are to be found 56 per cent—the survivors from childhood plus those who have acquired the disease in this age period. In the age group past 45 are to be found only 16 per cent, of whom 13 per cent were first afflicted before and 3 per cent after age 45."—*A.M.A. News* December 31, 1942

SOCIETY FOR ORAL DIAGNOSIS

The next meeting of the New York Society for Oral Diagnosis will be held on February 17 at 9 p.m. in Squibb Hall, 745 Fifth Avenue, New York City.

Members of the medical and dental professions are cordially invited.

PARTIALITY

Medical papers that I like best
Are always, if the truth be told,
The ones that just corroborate
The views that I already hold!

ment is to be considered. The more important question is whether the pharmacology of the drug is to be considered in the light of a specific enzyme detoxifying histamine, or in the light of a nonspecific protein.

Experimentally, the author, in several studies, was unable to find precipitins to histaminase in treated serum or demonstrate any increase in the circulating antibodies of sensitized guinea pigs, protected, in 50 per cent of the cases, from anaphylactic shock by histaminase. However, I could demonstrate that the protective action against anaphylaxis in guinea pigs was even greater, if human serum rather than histaminase was used—which seems to speak poorly for any supposed specific action on the part of histaminase.

Clinically, the fact that results obtained were just as good, whether treatment was preseasonal or coseasonal, logically seems to indicate that histaminase effects are nonspecific in nature. Rose,¹¹ looking for a decrease in the blood histamine of patients treated with histaminase, could find no such decrease, which would have suggested a specific detoxifying capacity, *in vivo*. On the other hand, Williams *et al.*,¹² investigating rabbit's blood, found that histaminase caused a drop in the blood histamine within two hours, but returned back toward normal within eight hours. Rose's observation suggests a nonspecificity to any histaminase activity, whereas Williams' observation suggests that the action of the substance, as far as histamine in the blood is concerned, is short-lived and immediate. Neither suggests any possible storage of histaminase for later use, which is what would have had to take place in our preseasonal patients who were benefited, if we were to consider the action a specific one. Logically, the results therefore suggest a nonspecific action.

The reactions to histaminase therapy are at times quite painful and occasionally may produce fever. Although they are not serious, they do not justify the indiscriminate use of the substance.

Conclusions

1. Histaminase was used, intramuscularly, in treating 69 observed cases of hay fever in 1941. The gross percentage benefited was 39.1 per cent. Those with fair to excellent results numbered but 28 per cent.

2. The percentage of patients benefited was approximately the same under preseasonal and coseasonal therapy.

3. A relatively higher percentage, 56 per cent, obtained relief from histaminase if the patients had never had any pollen therapy in past years. A much lower percentage, 27.7 per cent, was obtained for patients who had had previous years of successful pollen therapy.*

TABLE 1.—HISTAMINASE THERAPY INTRAMUSCULARLY IN
RAGWEED POLLINOSIS CASES

Histaminase in Cases Treated	Number of Cases Reported	"Better than Number Last Year"	Percentage
Preseasonally	18	7	38.8
Pre- and coseasonally	46	18	36.9
Coseasonally	5	2	40.0
Total	69	27	39.1
Without any previous pollen therapy	25	14	56.0
With previous pollen therapy in:			
(a) Cases with good results from therapy	36	10	27.7
(b) Cases with poor results from therapy	9	3	33.3

of the cases, and since pollen therapy benefited 36 of these 44 cases, it meant that histaminase had to be effective in order to compete with or improve the results.

In the group of 25 patients who had had no pollen therapy, 56 per cent of the cases benefited. Those who had had previous pollen therapy were subdivided into two groups: 36 who had benefited from pollen therapy and 9 who had not. The results were slightly better in the group which had not benefited from pollen therapy. In the group of 36 cases which had benefited from previous pollen therapy, histaminase benefited but 27.7 per cent during the 1941 season. A "carry over" beneficial effect from several years of pollen therapy, which one might have expected, was not definitely evidenced in the results.

Those cases treated on a strictly preseasonal basis (injections terminated before August 20) fared approximately the same as the cases treated on a pre- and coseasonal basis or those treated only coseasonally: 39 per cent, 37 per cent, and 40 per cent, respectively. The results were in no way comparable to those generally obtained by using pollen therapy. The season was admittedly one of the worst in years for sufferers in general. This made it especially difficult for histaminase, competing, as it were, with results from pollen therapy obtained during a much less severe season. At the same time, the unusually severe season offered a better test for a substance which would compete with pollen therapy in relieving hay fever.

Summary

Summarizing the results obtained in 1941, during which histaminase was used in the treatment of hay fever, the following may be said:

Coseasonal results, 40 per cent in 1941 obtained in but a small number of cases, were less encouraging than those obtained in 1940, but were not a total failure. There was no essential difference in the results between preseasonal therapy and co-

seasonal therapy. A significantly higher figure, 56 per cent, was obtained in that group of patients who had not had any previous pollen therapy. Cases who had had previous pollen therapy with or without good results fared much worse.

Discussion

The fact that histaminase was experimented with during a most severe season has been mentioned. Daily pollen counts for 1940 and 1941 show a much higher average for a greater number of days during the 1941 season. Symptomatically, the large majority of histaminase patients who were troubled during the 1941 season manifested their symptoms when the pollen counts were highest. Control patients under routine pollen therapy fared better than histaminase cases. This important difference between the results obtained from pollen therapy and histaminase is demonstrated by the gross figures in Table 1. Pollen therapy usually gives 80 to 85 per cent beneficial results. However, the figures do not tell all, for they indicate about a 40 per cent successful result from histaminase therapy. In terms of quantitative relief, routine charts of the symptoms of patients plus personal questioning do not indicate that more than 28 per cent had fair to excellent results. The other 12 per cent were simply better than last year although still suffering considerably. (Those pollen cases who had had good or excellent results in past seasons and who fared somewhat worse on histaminase, but still were much better than before any therapy, since this might have been attributed to a "carry over" effect, were not included in the "Better Than Last Year" results or the 28 per cent figure just mentioned. They had to be better under histaminase for this substance to receive the credit.)

Experience has demonstrated that some patients do not do well on pollen therapy. Some of these were benefited by histaminase. This fact should not be considered an argument in favor of the specific detoxifying power of histaminase for histamine, *in vivo*. There are many instances in medicine in which specific conditions are relieved by nonspecific measures—i.e., schizophrenia by metrazol shock, etc. This may be such an instance. The fact that of 25 patients who had never had previous pollen therapy, 56 per cent were benefited by histaminase is significant. Some might hastily judge the results to be a psychic effect, which is not too likely, considering that 28 per cent of those who had had previous pollen therapy and had benefited from it felt that they were even better under histaminase without pollen therapy. However, the author feels that unquestionably, with histaminase, as with most other medications, some psychic ele-

about normal, began to rise to about 101 F.; the patient was nauseated; the lungs were clear; there was no diarrhea; the stools were well formed, and there was no abdominal pain. Since it was believed that this was a drug fever, sulfaguanidine was discontinued. On October 13 the patient was given a blood transfusion of 350 cc. During the last week, dehydration became more marked; there was increasing azotemia, and on October 20 the patient lapsed into profound coma; the breathing was deep and of the Kussmaul type. Some coarse scattered rales were noted over the left lower lobe, but there were no signs of definite consolidation. The heart sounds were muffled; reflexes were abolished, and there was evidence of tarry stools. The patient died the same day.

Discussion

DR. EMANUEL APPELBAUM: The outstanding symptom on admission in this case was a severe diarrhea. Because of a rather abrupt onset and a history of a similar disease among associates, a diagnosis of an acute intestinal infection seemed logical. The azotemia and acidosis were regarded as secondary to the diarrhea and the dehydration. Following treatment with sulfaguanidine for six days, there appeared to be a definite clinical improvement. When the temperature began to rise on the seventh day, the possibility of drug fever was considered and the sulfonamide was discontinued. While there was a history of heart disease, there was no evidence of myocardial failure during this admission. Actually, not too much attention was paid to the patient's heart.

After nearly two weeks' observation it became obvious that the patient was really getting worse, although the diarrhea was apparently under control. The dehydration persisted and the lethargy increased. The blood picture showed a progressively mounting azotemia, a persistently low carbon dioxide combining power, and hypocalcemia. It was at this point that I suggested the diagnosis of uremia with uremic colitis.

The records of his previous admissions to Bellevue Hospital were then reviewed carefully. These revealed the following facts:

The patient's first admission was in May, 1939, for an infection in the stump of his amputated leg. He gave at that time a history of diabetes of twelve years' duration. However, there was no glycosuria, and the blood sugar was 114 mg. per cent. The blood pressure was 170/100. The second admission was in August, 1941, for generalized edema and dyspnea on

exertion. His heart was moderately enlarged. The blood pressure was 170/110. The urine had a specific gravity ranging from 1.004 to 1.025, with albumin to 4 plus, a trace of sugar, and numerous hyaline and granular casts. The blood chemistry showed a sugar of 125 mg. per cent, cholesterol of 170 mg. per cent, and nonprotein nitrogen of 34 mg. per cent. The serum albumin was 3.8 Gm. per cent, and the globulin 2.3 Gm. per cent. The case was regarded as an instance of hypertensive heart disease. Prompt improvement followed the use of digitalis and diuretics. Following three weeks' treatment the patient was discharged. He was readmitted in November, 1941, with the same symptoms—namely, edema and exertional dyspnea. The blood pressure was 168/98. The urine showed a specific gravity of 1.018, 3 plus albumin, and a few finely granular casts. There was no glycosuria. The glucose tolerance test was as follows: fasting blood sugar, 60; after one hour, 114; after two hours, 100. A diagnosis of intercapillary glomerulosclerosis was entertained at that time. The patient responded to treatment for cardiac failure and was discharged in about a week. The subsequent four admissions, between January and August, 1942, were all mainly for progressive edema. The blood pressure ranged between 160/100 and 185/110. Albuminuria and cylindruria persisted. There was no azotemia and no evidence of diabetes. A glucose tolerance test repeated during his fourth admission was as follows: fasting blood sugar, 75; after one-half hour, 84; after one hour, 125; after one and one-half hours, 139; after two hours, 156. A repeat glucose tolerance test a few days later showed the following values: fasting blood sugar, 106; after one-half hour, 100; after one hour, 148; after one and one-half hours, 165; after two hours, 116; after two and one-half hours, 108; after three hours, 95. Urine specimens were all simultaneously negative for glucose. The patient responded each time to treatment for congestive failure.

It is noteworthy that in 1941 some form of renal disease was suspected. Because of the marked edema, albuminuria, hypertension, and a previous history of a mild diabetes, we suggested then a diagnosis of intercapillary glomerulosclerosis. As you undoubtedly know, in this condition the diabetes, which is as a rule mild, comes first and is followed by hypertension and the urinary syndrome. Some of the clinicians, however, felt at that time that we were dealing with a straightforward case of hypertensive heart disease in failure. Indeed, the case was treated as such, and the patient showed prompt and marked improvement.

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

Date: December 3, 1942

Conducted by: Dr. Emanuel Appelbaum

DR. FRANK J. RUMMEL: This was the eighth Bellevue admission of a 50-year-old white man, who was admitted to Bellevue Hospital on October 1, 1942. His chief complaint was diarrhea of ten days' duration and the passing of brownish watery stools, without blood or mucus, twenty-four times in twenty-four hours. He also complained of an intermittent, dull, supra-umbilical pain which preceded bowel movements and which was relieved by the passage of stools. There was no nausea or vomiting; the patient had never had diarrhea before. At about the same time four or five of his associates experienced diarrhea. The patient's appetite had been poor since the onset of his present illness. He had lost considerable weight during the ten days prior to admission. He slept poorly; there was no history of headache; there was slight cough but no dyspnea. The patient experienced occasional nocturia and there was urinary frequency during the day—three to four times. There was no evidence of skin rash. The patient had experienced hiccoughing during the three days before admission. During his previous admissions he had presented a picture mainly of cardiac failure, for which he was treated successfully with diuretics and digitalis. In 1939 his right leg was amputated because of gangrene.

On admission the temperature was 97.8 F.; pulse, 96; respirations, 20; and the blood pressure ranged between 110/70 and 150/80. The patient was a well-developed, lethargic, dehydrated white man in no acute distress. The skin was flushed. There were marked unilateral excoriations of the buttocks, multiple crusted lesions on the body, and pigmentation of the lower abdomen. The eyes, ears, nose, and throat were negative except for the tongue, which was beefy red and furred. The neck was supple; there was no tracheal deviation or lymphadenopathy. The thorax was symmetrical; the lungs were hyperresonant throughout, with distant breath sounds; there were no rales. The heart was enlarged to the left; there was regular sinus rhythm; the sounds were distant. There was present a systolic murmur at the apex. The abdomen was soft; there was

no tenderness; no organs or masses were palpable. The rectal examination was negative. There was no edema, cyanosis, or clubbing of the extremities.

Laboratory Data.—The red blood cells averaged 4,100,000, with 11 Gm. of hemoglobin; the white blood cells were 7,650 on admission and later averaged about 18,000, with 75 per cent polymorphonuclears, 20 per cent lymphocytes, and 5 per cent monocytes.

Urinalyses: Specific gravity ranged from 1.008 to 1.015; reaction for albumin was 1 to 4 plus; reaction was negative for glucose; microscopic examination revealed a few hyaline and granular casts and a few white blood cells per high power field.

The blood nonprotein nitrogen tests were reported to be 72 to 128 mg. per cent; the blood creatinine was 2.5 mg. per cent; chlorides, 564; carbon dioxide combining power, 18 to 30 volumes per cent; calcium, 5.9 mg. per cent; serum albumin/globulin ratio, 2.5/3.6 Gm. per cent; fasting blood sugar, 80 mg. per cent. The stool cultures were negative for ova, parasites, dysentery, paratyphoid, and typhoid; the guinea test was positive on three occasions and negative on one occasion. The erythrocyte sedimentation rate was 24 mm. per hour on October 2; 3 mm. on October 9. The blood agglutinations were negative for typhoid, paratyphoid, Brucella, and Weil-Felix on October 2. On October 8 the blood agglutinations were positive for typhoid O antigen in dilution of 1:20 and were negative for H antigen in all dilutions. The blood Wassermann was negative. Blood cultures were reported to be negative. A roentgenogram of the chest taken on October 13 showed slight engorgement of the lower lobe of the right side; there was also moderate cardiac enlargement. An electrocardiogram taken on October 13 showed sinus rhythm, left axis deviation, and left bundle branch block.

Course.—The patient was given sulfaguanidine and the dehydration was treated with forced fluids. On October 6 he was much improved, taking fluids and food by mouth and having one bowel movement per day. There was no abdominal pain, nausea, or vomiting and he appeared relatively hydrated. Two stool cultures were reported negative by that time. On October 7 the temperature, which had been

likely explanation of this would be a coronary sclerosis accompanied by myocardial lesions. The presence of a left bundle branch block would bear out this surmise.

The diarrhea which was so prominent at the beginning of the terminal illness apparently improved and ceased entirely before death occurred. This would therefore seem to have been a transient episode which might or might not exhibit identifiable lesions in the colon.

Diagnoses.—Cardiac fibrosis, coronary sclerosis; chronic diffuse glomerulonephritis; diffuse degenerative arteriosclerosis; catarrhal colitis.

Discussion of Pathology

Gross Findings.—DR. P. CAREY WHITEHEAD: At autopsy there was moderate edema of the left foot and ankle and the soft tissues overlying the sacrum. On the right side the leg was amputated at the mid thigh, and the stump was well healed. No other significant changes were found.

The peritoneum and pleural sacs were free of fluid.

The pericardium contained no fluid, but there were numerous fresh fibrinous adhesions between the pericardium and epicardium. The heart was enlarged, and weighed 600 Gm. The increase in size was due largely to dilatation and hypertrophy of the left ventricle. An aneurysm of the anterior wall of the left ventricle was found, measuring 4 by 3 by 2.5 cm., at the site of a healed infarct. On the endocardium of the aneurysm were found two old thrombi.

In the aorta there was marked arteriosclerosis, and the coronary arteries showed marked sclerosis, with narrowing of the lumina of all of them, and occlusion of the descending branch of the left coronary about midway between its origin and the apex.

The lungs were the seat of lobular pneumonia in the lower lobes.

The liver was yellowish and greasy on section. The gallbladder contained several pigment stones; the mucosa was found to be thickened.

On opening the gastrointestinal tract a small erosion was found in the esophageal mucosa in the lower one-third. The distal one-half of the colon contained free blood, and several areas of ulceration were found in places in this portion of the bowel. The rectum contained several lesions.

The left kidney was found to be slightly enlarged, and weighed 100 Gm. At the time of the autopsy it was very pale and had a yellowish-pink hue. The surface was finely granular after stripping the slightly adherent capsule.

The cortex and medulla could not be differentiated. The cortical striations were faint

FIG. 1. Photomicrograph of different stages of intercapillary glomerulosclerosis. In Fig. 1, two of the glomeruli contain the characteristic ball-shaped deposits of connective tissue which begin in the intercapillary connective tissue.

in places and absent in others. Examination of the renal artery showed it to be moderately sclerotic. The right kidney weighed 150 Gm. but was otherwise similar to the left. These findings were not considered characteristic of any one disease process because they have points common to chronic glomerulonephritis, arteriolo-nephrosclerosis, and intercapillary glomerulosclerosis.

No significant changes were found in the other organs.

Microscopic Findings.—DR. IRVING GRAEF: The essential pathologic findings relevant to the clinical symptoms and signs were limited to the heart, pancreas, and kidneys.

The microscopic preparations of the left ventricle and coronary arteries confirmed the gross impression that there was an organized, old thrombus in the anterior descending branch of the left coronary artery. Both the left and the right coronary arteries were the seat of considerable atherosclerosis, with variable narrowing of the lumina. The intraventricular thrombus was fused imperceptibly with the scarred endocardium overlying the healed myocardial infarct.

In the pancreas, none of the islands of Langerhans in a single sample section exhibited hyaline degeneration like that seen in diabetes.

The renal lesion is a complex one presenting a variety of changes which may be listed in the order of their importance. There is universal arteriolar sclerosis of the type commonly seen in benign arteriolar nephrosclerosis. The glomerular changes vary. There are completely hyalinized and fibrotic glomeruli, which may well be the end stage of ischemic fibrosis secondary

In summary, this patient was admitted with a severe diarrhea, which was regarded at first as an intestinal infection associated with dehydration and extrarenal azotemia. He was treated with sulfaguanidine, with apparent improvement. It soon became clear that the patient was getting progressively worse. We then suggested a diagnosis of uremia with *uremic colitis* on the basis of a chronic glomerulonephritis. This led to an investigation of his previous records, in which evidence of renal disease was found. On one occasion a diagnosis of intercapillary glomerulosclerosis was suggested. However, congestive failure seemed to dominate the clinical picture during the previous admissions. The patient finally died in a state that appeared to us to be like a progressive uremia.

DR. HERMAN O. MOSENTHAL: The interpretation of the signs and symptoms of this case presented three aspects. These are: (1) diabetes mellitus; (2) uremia; and (3) cardiac failure.

The bald statement is made that in 1939 there was a history of diabetes of twelve years' duration. There is every indication in the records that this diagnosis is an unwarranted assumption. All the fasting blood sugars were normal, as were at least two glucose tolerance tests. In diabetes the fasting blood sugar may even be within normal limits but the carbohydrate tolerance test never is. The gangrene of the leg, the coronary changes, the albuminuria, and the moderate elevation of blood pressure are all lesions that are frequently complications of diabetes, but that is no reason to insist that the patient had diabetes when the crucial diagnostic procedure—the sugar tolerance test—is negative.

The conclusion that the diarrhea which initiated his terminal illness was a uremic manifestation is a brilliant thought and may be correct, though an appraisal of the clinical features makes me hesitate to accept it. In the first place we are not clear as to the exact definition of uremia. Ascoli's time-honored concept, which is often set up as a standard, describes uremia as a symptom complex consisting of signs of irritation and stimulation of the central nervous system associated with evidences in the urine of renal damage. These ideas were formulated before any tests for renal function were available and it is now realized that most of the cases Ascoli presented in his monograph were in reality instances of hypertensive encephalopathy. Our case had no symptoms of central nervous system injury, so that there is no evidence of uremia or pseudo-uremia (i.e., hypertensive encephalopathy) on

that score. The more modern definitions of uremia explain it as a state associated with a maximal impairment of renal function. In this patient the curtailment of kidney activity had not reached a stage approaching a 90 to 95 per cent loss of kidney efficiency requisite to justify the existence of retention uremia. The blood cell count was 4,100,000; it is invariably much lower when the kidney function is greatly diminished; in fact, a marked anemia precedes the onset of retention uremia in chronic nephritis for many months. The blood creatinine level of 2.5 mg. per cent is much too low to coincide with a maximal degree of impairment of renal function. Finally, a urinary specific gravity as high as 1.015 is not found when renal reserve power is completely abrogated. For all these reasons I believe uremia may be eliminated as a cause of disease in this case. A detailed discussion of this problem is very necessary because the diagnosis of uremia (and, for that matter, of diabetes) rests almost entirely upon the clinical findings and not upon the pathologist's examination.

As for the kidneys, there was a history of a long-standing albuminuria and hypoproteinemia—that is, a nephrosis. In addition there was a moderate elevation of blood pressure and impairment of kidney function. The two latter findings point to a chronic glomerulonephritis being engrafted on the nephrosis, which is a common enough occurrence. The supposed history of diabetes has led to the conclusion that this is an instance of intercapillary glomerulosclerosis, a lesion first described by Kimmelstiel and Wilson, and named after them. It is very difficult for a doctor, like me, largely concerned with clinical medicine, to arrive in the clear concerning "intercapillary glomerulosclerosis." Some pathologists claim that it occurs only occasionally in diabetics, while others claim that it is found in one-third of all diabetics and is the most reliable microscopic tissue investigation through which the diagnosis of diabetes may be suggested. On the other hand, all acknowledge that it is occasionally found in nondiabetics and some standard textbooks describe it as a prevalent lesion of chronic glomerulonephritis. If intercapillary glomerulosclerosis proves to have been present in this case, I believe it supports the thesis that this lesion may be found in nondiabetics.

The patient's major symptoms were evidently cardiac. He had time and again been described as a "hypertensive cardiac" case. The blood pressure, fluctuating from 170/110 to 150/80, was not high enough in *itself* to result in cardiac failure. There must have been another element in the situation to bring this about. Social Insurance in a Democracy

REINHARD A. HOHAUS, New York City

WHAT are the origins of the tragic upheaval the world is undergoing? What measures should be taken in the postwar period to prevent a recurrence? Many of you doubtless share my own sense of frustration in attempting to answer these questions. The underlying issues are too great and manifold for ready comprehension. Nevertheless, each of us is making every effort for a better understanding so that he may serve more intelligently in our great cause.

We know we are enlisted on the side of democracy in a fight to the finish. We know that we have had to learn again the great importance of certain principles we had forgotten in whole or in part. We now realize, more clearly than before, that democracy is more than a political creed, more than government of the people and by the people—that it is a way of life dedicated to the freedom and dignity of the individual.

It is indeed fitting that democracy is coupled with the "dignity of the individual," because that expression conveys so beautifully the profound philosophy underlying the proper democratic way of life. Thus it reminds us that the individual by his very nature is a free man and that a democratic form of society means a community of free people banded together in a spirit of mutual respect and self-discipline. Dignity of the individual also calls to mind those spiritual values with which man is endowed by his Creator—values which can be neither granted nor revoked by the State. It confirms our conviction that the common man, together with his fellow-citizens, has the ability and power to direct and mold the future of his country. But it also tells us with equal fervor that with this freedom and power goes responsibility, and that much is expected of the individual if he is to be worthy of the rights with which he was born.

And in so doing, it places definite obligations upon the individual in at least three directions—to himself and his family, to those for whom and with whom he works, and to society as represented by his fellow-citizens and himself and the agencies they have set up for their common good.

In the forefront of these responsibilities is that

of providing a reasonable amount of security against the major hazards of life. They include death, dependent old age, accident, sickness, and unemployment. The role which ordinary, industrial, accident and health, and group insurance can and do play in enabling the individual to secure protection for himself, his family, and his coworkers, and the remarkable extent to which our citizens have availed themselves of the opportunities afforded by them, are too well known to you to warrant repetition. That, however, is only part of the story. It still leaves untouched that area in which the individual as a member of society also assumes certain responsibilities for the well-being of his fellow-citizens in times of adversity.

Function of Social Insurance

The depression years brought general agreement that changes in the social and economic structure of our country had made inadequate some of the old methods by which society attempted to meet its obligations, and that major innovations were needed. One of the results was the adoption of the social insurance approach for certain of the major hazards. While that approach was new to this country, it can hardly be considered as a change in basic philosophy, since it is essentially an attempt to set up a more orderly and efficient procedure by which society will continue to carry out responsibilities which it had assumed in the past through other channels.

Social insurance is generally recognized in democratic countries as an essential part of national life and it should have even greater importance when peace is finally restored. Because of that and the many ways in which it affects the institution of life insurance, directly or indirectly, it seems timely to review together some of the questions concerning its present and future status in our country.

Social insurance, as we in America are coming increasingly to understand it, is a new sphere of activity which derives its being and inspiration from a number of widely differing sources. Foremost among these are the fields traditionally ascribed to the social worker, the actuary, the economist, and the fiscal administrator. While drawing heavily on all these, social insurance does

FIG. 2. Photomicrograph illustrates sagittal section through the glomerulus and the terminal portion of the afferent arteriole. The arteriole exhibits considerable sclerotic change in its wall and the glomerulus is the seat of diffuse thickening of the intercapillary connective tissue. Empty patent capillaries may be seen at the periphery of the glomerular tuft. Poor state of the tubules is due to postmortem change, as the necropsy was performed five days after death.

to arteriolar sclerosis. But in addition there are numerous glomeruli presenting a distinctive type of focal or diffuse intercapillary fibrosis (Figs. 1 and 2). Special stains (Masson's Trichrome or the Azan-Carmine stain) show that these fibrous deposits are truly collagenous. The milder lesions furnish the opportunity to locate this process in the intercapillary connective tissue. In the less advanced lesions there is found one or more of the typical spherical "ball-shaped" lesions separating the loops of a single glomerulus. The tubular changes vary from zones of marked atrophy, where the tubules are caught and compressed in scar tissue, to areas of dilatation and hypertrophy of isolated cortical nephrons.

The interpretation of the findings in this case which seems most valid would depend on placing this renal lesion in the new category of renal disorders designated as "intercapillary glomerulosclerosis." This was first described by Kimmelstiel and Wilson,* who observed its occurrence in a group of patients who had the distinctive symptoms noted in this patient's record—to wit: mild diabetes, profound albuminuria, plasmaphoresis, edema, and hypertension. As in this patient, renal insufficiency

may be relative rather than absolute, and death often occurs in a picture reflecting renal insufficiency and heart failure together.

Distinctively, albuminuria is usually profound in the course of the disease, presumably owing to the alterations in the glomeruli, and associated with plasmaphoresis, which was also reflected in this patient's serum albumin-globulin ratio. The question of the diabetes cannot be adjudicated on our morphologic evidence.

It is proper to state that there are some who deny that this lesion is limited to diabetics with hypertension.* On reviewing 75 diabetic patients that have come to necropsy at Bellevue Hospital, I found 12 cases with this renal lesion, an incidence of 16 per cent. Among the 12 cases in this series, there were 5 with clinical signs and symptoms; 4 others had equivocal signs and symptoms; while 3 additional cases had only hypertension. In all 12, arteriolar nephrosclerosis was a consistent renal lesion as noted by Horn and Smetana, too. In some there was an associated pyelonephritis. In the past the clinical diagnosis of amyloid disease was often considered as the best working diagnosis.

With regard to the fall in this patient's blood pressure during the last admission, it may be related to the extensive myocardial infarct.

Anatomic Diagnoses

INTERCAPILLARY GLOMERULOSCLEROSIS.

ARTERIOLO-NEPHROSCLEROSIS.

Dilatation and hypertrophy of the heart, chiefly the left ventricle.

Acute fibrinous pericarditis (uremic).

Hemorrhagic colitis and proctitis (uremic).

Lobular pneumonia, both lower lobes.

Generalized arteriosclerosis, marked.

Renal arteriosclerosis, moderate.

Coronary arteriosclerosis with occlusion of anterior descending branch of the left coronary artery.

Healed myocardial infarction with aneurysmal dilatation of the anterior wall of the left ventricle.

Mural thrombi, left ventricle.

Fatty infiltration of the liver.

Chronic cholecystitis with cholelithiasis.

Ulceration of the esophageal mucosa.

Edema, left foot, left ankle, and sacrum.

Healed mid thigh amputation, right.

"A medical paper," says Dr. Joe White, of Fort Worth (Texas), "should be like a lady's dress—long

enough to cover the subject, but short enough to be interesting."—*Texas State Journal of Medicine*

buying additional protection from private sources through their private means."

However, much remains to be done by way of developing a proper understanding among those concerned as to the nature of the protection which social insurance should aim to provide, and the way in which private insurance and other agencies can operate to supplement it—and perhaps even furnish it in part. Both types of protection—social and private—have to function in an economic, social, and political environment that is dynamic rather than static. Both must be capable of mutual adjustment as circumstances change and new developments arise. Properly conceived, their functions are complementary rather than competitive. They should engage each other like well-adjusted gears cooperating to a common end, not clash like antagonists competing for survival.

Social Insurance in the United States

Social insurance as practiced or discussed in the United States may be divided into the following categories:

1. Provision for old age and for dependent survivors at death.
2. Unemployment insurance.
3. Health insurance.

1. OLD-AGE AND SURVIVORS' INSURANCE

The Federal Old-Age and Survivors' Insurance Plan incorporated in the United States Social Security Act through the amendments made in 1939 falls in the first category. It represents a decided improvement over the plan originally adopted, especially in regard to the revised scheme of benefits. The social adequacy principle is recognized in the primary benefit formula and in the provision of supplemental benefits for wives and young children. Consistent with that principle are the provisions that monthly benefits are suspended when the person otherwise entitled to them is employed, and that survivors' benefits are not paid to a widow simply because she is a widow, but only if she has young children or has reached age 65. The decision to include employees earning over \$3,000 a year to the extent of \$3,000 a year in preference to excluding them completely was probably based on practical administrative considerations. This has resulted in a fortunate by-product in that the plan has come to be looked upon as truly national rather than one for a particular class, as is the case with at least some foreign plans.

However, the Federal plan is still far from perfect in a number of ways. Changes which should be made when technical and other practical considerations permit, include:

1. Simplification of the benefit and insurance status formulae.
2. Enlargement of the scope of coverage to bring in groups of workers now excluded.
3. Provision for those who become "prematurely superannuated" shortly before age 65 and probably for at least some of the others who become totally and permanently disabled.
4. Further emphasis on "social adequacy," and less on "individual equity," as the benefit criterion.

In addition, more light is needed on the principles which should underlie the financing of the plan.

The Federal Old-Age and Survivors' Insurance Plan and voluntary insurance (including individual and group plans) are each better able to accomplish its objective because of the existence of the other. Experience of the past three years clearly indicates that the basic layer of protection of the Federal plan and the various forms of protection available through private insurance enable and encourage the individual to make those additional provisions for himself and his family which democracy calls upon him to accept as his individual responsibility.

2. UNEMPLOYMENT INSURANCE

While the developments in the old-age insurance field since 1935, when the Social Security Act was originally enacted, and the outlook for further improvements are quite encouraging, we find an entirely different situation as to unemployment insurance.

Here the "social adequacy" philosophy has hardly begun to be appreciated, much less applied. Though there has been a comprehensive attempt on the part of the Federal and State governments to meet a very important part of the problem of unemployment through social insurance, the plans in operation are not based on a proper understanding of the social insurance approach. Benefits are too closely geared to prior wages. Except in the District of Columbia, family responsibilities are completely ignored. Such recognition as given to the social adequacy principle is mainly through the prescribed minimum benefit for those who qualify, irrespective of family status. In general the benefit formulae used result in "over-adequate" benefits for some and decidedly inadequate benefits for others—especially those with dependents, who should be the first consideration of any government which regards the family as the basic unit in its social structure.

Because of abnormal employment and other conditions due to the war, these weaknesses in our unemployment compensation laws have not forced themselves as much on public attention as

not too closely parallel any single one of them. Rather is it a new creation calling for a social outlook that diverges significantly from the familiar paths of the ordinary social worker, requiring an actuarial technic that may sometimes seem rank heresy to the orthodox private insurance actuary, and introducing certain economic and fiscal concepts which may be outside the purview of the "classical" textbooks we read in our student days. Yet through this very process of leaning heavily on and still taking considerable liberties with orthodox theory in all these fields, social insurance represents a new instrument which is being forged to meet certain social problems that must be solved, if we are to maintain our democratic way of life.

There is ample evidence of lack of agreement among experts concerning various major questions present in this new field. Be that as it may, I am convinced that today there is a very encouraging understanding of the proper role of social insurance among the workingmen for whose benefit it exists. The American workingman realizes instinctively that the primary aim should be the assurance of a basic minimum of protection to meet the most fundamental needs of himself and his family—to remove the spectre of want in the day of misfortune over which he has no control. But he certainly does not want that basic protection endangered by an unstable program promising more than it can perform. Nor does he want it subject to humiliating conditions that carry a stigma of pauperism.

Instinctively, too, the worker knows that between government as the guarantor of his personal democratic liberties, responsible for safeguarding the economic and political conditions necessary for their maintenance, and government as a totalitarian monster reaching out for mastery over his body and soul, there is a somewhat problematic no-man's land where eternal vigilance is the order of the day. He knows that in this region there must always be a jealously guarded boundary between what government may and may not do; and that any material departure therefrom may have the unintended effect of imperiling democracy itself. He knows likewise there must be an area in which individual initiative and private enterprise should have ample scope to make their fitting contributions to human advancement, not only materially but in the realm of character. He knows that he, as well as the government, must be willing to accept responsibilities for the well-being of himself and his family.

Principles of Social Insurance

While there is still much disagreement on various aspects of social insurance, we do find in-

creasing acceptance of the following principles:

1. The purpose of social insurance should be to provide, through a government-operated or sponsored plan, protection against one or more major hazards of life which are sufficiently widespread throughout the population and far-reaching in effect to produce large dependency problems for society, and so become "social" in scope and complexion.

2. The protection should be afforded on a dignified basis making for self-respect—usually as a legal right.

3. Being designed to serve primarily society as a whole, little or no latitude should be permitted the individual insured regarding the kind and amount of the protection he may have, or the price to be paid for it.

4. The measure of protection should be "social adequacy" for the insured and their families—that is, it should represent, as far as practicable, a basic layer of protection. "Social adequacy" usually makes it impractical to have "individual equity" for the insured in the sense of a mathematical *quid pro quo* return on account of the contributions made by or on behalf of the individual.

5. With individual equity not required, membership in the plan should be compulsory to minimize self-selection, abuses, and anomalies. Compulsion is also desirable in order to obtain the widest practicable coverage of the population.

Relation of Social to Private Insurance

With benefits related primarily to the individual's and his family's probable minimum needs to keep them from becoming public charges, it is obvious that the level of protection in social insurance may be, and usually is, quite different from that set for the insured in either individual or group insurance. Social insurance is compulsory with uniformity of benefits. Private insurance is voluntary, with each insured setting his own standards of security as to both plan of coverage and amount. This distinction cannot be overemphasized because it makes clear why social insurance and private insurance can, and should, go hand-in-hand in providing the security the individual desires to meet his own needs and circumstances.

The responsibility which is left with the individual has been well stated by Mr. Altmeyer, Chairman of the Social Security Board, in these terms:

"A social insurance system does not and need not undertake to furnish complete protection to all whom it covers under all circumstances. The social insurance approach is to assure that the benefits would provide a minimum protection, leaving to the individuals the responsibility of

cash benefits in event of accident or sickness, for hospital expenses, or for benefits in event of surgical operations, while plans offering insurance in one form or another for general medical care have met with a relatively limited response?

Should medical care protection be on the basis of providing the services in kind, or should it be on a reimbursement basis for part or all of the charges to the individual by the physician or institution in question? If services in kind, how should the doctor be compensated—by salary, on a per capita panel basis, or on a fee-for-service basis? Should the plan be entirely under medical control or should there be lay participation in its management?

Should a health insurance plan limit itself to care for the disabled, or should it also include health education, periodic examinations, and other preventive work supplementing, or even replacing, that now being done by Federal and State Public Health and other agencies?

However you answer these and other related questions too numerous to mention, you can probably find recommendations of experts to support your conclusions. Even if we turn for light to Great Britain, which adopted its first National Health Insurance Act in 1912, we find the whole matter under intensive study by a special Inter-Departmental Committee now conducting a comprehensive survey of social insurance and allied services under the Chairmanship of Sir William Beveridge. The scanty reports being received indicate the likelihood of recommendations for very major changes in the present setup.

The central problems that call for solution have been compressed by Owen D. Young into the following statement:

"The problems of illness are medical, economic, and social. The sick person needs a doctor, and perhaps a hospital. He also needs food and shelter, for himself and family, at the very time when the illness may have cut off his income. And he needs these things by methods not demoralizing to himself or the community, not unfair to the medical profession and not incompatible with the essentially individual nature of medical care."

Thus a cash benefit to replace part of the loss of income during disability is by no means the only, or even the major, phase of the health problem. Judging from the discussion and controversy that have centered around it, the provision of medical care, on this continent at least, would seem to be a far more troublesome and perplexing matter, not only for the average citizen who wants it, but for the numerous agencies concerned in providing it. It is a problem closely bound up with the vital interests of important sections of

the population and with the fundamental relationships which they have to each other. The various branches of the medical professions, their patients, hospitals, employees and their employers, the self-employed, insurance companies, fraternal societies, hospital service plans (which probably have about ten million participants) and other private organizations already making available benefits under the category of medical care or related services, the general taxpayer, government at various levels—are all deeply involved. And when medical care is tied in with the problem of cash benefits the difficulties are only multiplied and enhanced. And if not tied in, then one set of difficulties disappears only to be replaced by another set.

(a) *Social Adequacy in Relation to Health Insurance.*—In view of the foregoing comments, it is not surprising to find that the social insurance principle of social adequacy encounters more complications in attempting to apply it to the current situation in the health field than are present in the old-age, survivorship, and unemployment fields. One reservation should, however, be noted. These added complications probably do not apply to the preventive aspect of that complex of individual and community health problems of which "health insurance"—in the sense of a cooperative effort to secure cash benefits or provide medical care during disability—can claim to be but a partial answer.

The "preventive" aspect in its more elementary phases—sanitation, epidemic control, and various other normal activities of the public health authorities—has long been regarded as a proper field for governmental action. We now find prevention no longer limited to just the avoidance of disease, but also including the more positive function of maintaining health and well-being at a high level of efficiency. It includes nutrition education, recreation, and physical training, no less than immunization and a yearly check-up. In this more advanced sense of a seeking after positive health we find government assuming an increasingly vital role—the importance of which has been greatly enhanced by wartime conditions. Here if anywhere, government does not need to be too meticulous about drawing a line between what is merely adequate, and what may be described as additional or supplementary. Positive health promotion of a public or community nature is one field in which an intelligent and nonoverlapping mutually beneficial "rivalry" between government and private enterprise is entirely practicable and of inestimable advantage to all.

On the other hand, where the question is one of definite health benefits—in cash or in kind—to disabled individuals, the determination of the

would otherwise be the case. In the postwar period they will doubtless become increasingly serious, until suitably dealt with. Their solution need not present insuperable difficulties. The main requirement would seem to be a wider application of the principles already being used in the Federal Old-Age and Survivors' Insurance Plan—e.g., a better social adequacy minimum, allowance for dependents, and employee contributions. A decided change in emphasis from "individual equity" to "social adequacy" for the benefits and a general sharing in the cost by employees, as well as employers, should also serve to dispose of the recurring "experience rating" controversy.

The present lack of interest in the unsound provisions of the existing unemployment insurance plans is doubtless due in large measure to the large funds which have accumulated under the State plans through a combination of very unusual circumstances. Such apparent surplus readily leads to unwise liberalization of benefits, which suggests the very discouraging prophecy that sound progress may only be expected when adversity hits the plans. This pessimistic outlook brings to mind an observation made many years ago by a great student of pensions, who, in discussing a somewhat similar situation for a government pension plan, said, "No one can plunder a deficit." However, some hope for earlier progress may be obtained from the fact that the desirability of a benefit formula related to family status has recently been advocated by representatives of at least two important agencies in the unemployment insurance field.

As for individuals supplementing the minimum protection of State plans by additional protection on a voluntary basis, no unusual or difficult problems are involved. The simplest and most direct method is to build up a cash reserve through one of the usual thrift channels. With personal thrift being recognized once more by the Federal government as a very worth-while quality through its War Bond and anti-inflation campaign, it is apparent that the great need for government action in providing protection during unemployment is the revision of State unemployment insurance plans along the lines which will make them social insurance in fact, as well as in name.

3. HEALTH INSURANCE

The third category of social insurance—health insurance—is still mainly in the discussion stage and we find here a very confused situation. Even some of the most fundamental questions are still to be answered. Thus there is disagreement as to the need for a compulsory plan of Government Health Insurance; as to the governmental agencies—Federal, State, or local—which should

apply the compulsion, if compulsion is to be exercised; how the responsibility should be apportioned between such agencies; and as to whether Government itself should set up the organization for rendering service, or merely require individuals to find or create organizations for themselves.

Indeed even as to the meaning of the expression "health insurance" we find differences of opinion. Some of us, in our innocence, may look upon it as simply a mechanism for providing cash benefits during illness, such as the plan recently adopted by Rhode Island. If so, that view is quite contrary to that of an organization which has for many years been in the forefront in the promotion of social insurance in the United States, as evidenced by the following extracts from an article the American Association for Social Security recently published concerning the Rhode Island plan.

"Of serious implications to the future of health insurance is also the fact that the program is not accompanied by any provision for medical services. Cash benefits and medical care are the two phases of the problem created by illness. To deal with one phase alone is valueless if the other is neglected, as has been proved by experience throughout the world. It is well known that the burden of doctors' and other medical bills is often heavier than the loss in wages. It is also axiomatic that the stoppage of wages and the duration of cash benefits must be kept to a minimum by abbreviating the period of illness through medical attention. . . . Any health plan which fails to include provisions for reducing the period of illness by adequate medical care is not only unnecessarily costly but both socially and medically unsound.

"... Ever since its inception, however, the Association has fought opportunistic or half-baked formulas and insisted that social security legislation follow tried and proven principles. Tested by these principles, the Rhode Island scheme reveals itself a dangerous deformity. All announcements to the contrary, health insurance in the United States is still to be born."

"Adequate medical care" in turn introduces other questions besides providing the services of a physician for the insured workman. Does it also mean such provision for his dependents? Does it extend to hospitalization of himself or his family? Does it embrace the cost of drugs, surgical appliances, glasses, etc.? Is maternity an insurable risk? Should provision be made for dental care?

What interpretation should be placed on the fact that millions of individuals have voluntarily become insured with insurance companies, hospital service plans, etc., for weekly or monthly

conventional methods of private practice in peacetime. What will be their attitude after peace is won and they and others in military and naval service return to civilian life?

The debate both within and without the medical profession as to the merits of the existing system of medical care and related services, and of various proposed modifications and alternatives, had been under way for some years prior to our entry into war. Various experiments have been made and some have been eminently successful. As to the others, either the results have been quite unsatisfactory or more time is needed before a definite conclusion is warranted. Even before the impetus of the war, the outlook was that some new procedures for providing medical benefits and distributing their cost would be forthcoming. As already noted, these trends may also be present in Great Britain which adopted the social insurance approach thirty years ago.

(d) *Determination of Any Federal Standards.*—At least some of the advocates of health insurance maintain that the Federal government should assume a more active role in making available a socially adequate minimum of medical care—a matter of very intimate and personal concern to every citizen—and in distributing its costs to lighten the financial burdens on the individual when he or one of his dependents becomes disabled. If such action is taken, what procedure should be used to determine the principles to be followed in deciding to what extent, if any, the social insurance approach is appropriate, and in formulating the Federal standards that are to be generally enforced? All of us will agree that they should not be dictated handed down by a supposedly wise and benevolent government, but rather the outcome of a more democratic procedure in which the interests most vitally concerned are encouraged to make their appropriate contributions.

Any widely acceptable standards can hardly do less than embody a broad consensus of opinion among the groups most vitally concerned, and much greater emphasis should be placed on the fact that these groups include insurance companies (stock and mutual), fraternal organizations, hospital service, and similar organizations for medical care. These institutions have a vast amount of very helpful experience and have made very striking contributions in aiding the individual to handle the economic problems which disability presents.

Without careful planning, the adoption of Federal minimum standards involves the risk of the nation finding itself saddled with a government scheme under which most private health plans will be eliminated, and available medical care, and accompanying cash benefits, will be

reduced to a level of uniformity providing less adequate benefits than would otherwise be available for many people. Any set of minimum standards should therefore make room for at least the best and most widely accepted of current practices. They should harmonize with, not run counter to, national psychology and aspirations. Existing practices or schemes that have achieved real success should therefore be closely studied to see how they may contribute to, and agree with, the appointed standards. Decentralization is of utmost importance to encourage the quality and flexibility which we will wish our procedures to have. Thus a system best fitted for a rural area may be entirely inappropriate for a large city with its concentration of population and vice versa. Other illustrations of the desirability of decentralization and flexibility will readily suggest themselves.

Accordingly, the various means that are admissible as an instrument for giving effect to the body of guiding principles and standards with reasonable economy and efficiency should be carefully and sympathetically considered. For the Federal government's prime interest should be the end to be served—an acceptable minimum of protection for all. It should be interested in means only to the extent necessary to ensure the swift and sure attainment of this end. It should itself operate such means only to the extent that the job cannot be done at least as well by other agencies, whether private or on a lower governmental level.

Conclusions

What, then, are our conclusions as to the present status and the future outlook of social insurance in our country?

As to old-age and widows' and orphans' benefits, our Federal plan has made a good start along sound lines. Desirable changes include those making the principles already present more effective and clarification of the present indefinite policy for financing the plan. Private insurance complements the Federal plan, and each better serves our citizens because of the existence of the other. Continued progress on the course already charted should be the aim for the future.

As to unemployment insurance, basic changes in principles and underlying philosophy are essential. These should come about before the postwar depression, which many foresee as inevitable, but unfortunately the present outlook for such a development is quite discouraging. One must turn for consolation and encouragement to the splendid way in which our countrymen have accepted thrift and "putting one's financial house in order" as a personal responsibility. The present great accomplishments in

proper role of private enterprise—including in that term mutual and stock insurance companies and other nongovernment agencies providing insurance based on the concept of equity for homogeneous groups—and of government plans based on the social adequacy philosophy presents problems still to be solved.

(b) *Alternative or Supplementary Protection.*—The goal of social insurance under the philosophy of "social adequacy" is a minimum basic layer of protection for all. While the function of government would be confined to the furnishing of such a *minimum*, many individuals will not only desire, but presumably be in a position to obtain, more than this. We have seen that individuals and groups of individuals can and do provide greater security for their dependents in case of death, and for old age and unemployment, by supplementing the government minimum through other channels. These "supplementary" provisions are in the form of protection in addition to, and usually independent of, the government benefits. They are not "alternative" provisions in the sense that they might combine the government's and the individual's measure of protection in one single program which would replace the government plan for the particular person involved. It will be recalled that extensive study was given some years ago to the question of having the Social Security Act permit an employer to "contract out"—i.e., to continue his employee retirement plan as an alternative to the Federal old-age plan, and thereby make it unnecessary for him to revise his plan on a supplementary basis to take into account the Federal benefits. It was concluded that this was not practical because of complications arising from the necessity of accumulation of reserves and other factors. However, when the benefit takes the form of medical care, quite a different picture is presented.

New problems arise if the government decides to extend social insurance to the field of health benefits and we are to retain the democratic principle of giving individuals the opportunity of "buying additional protection from private sources through their private means." These problems would seem to indicate that, in many cases at least, the function of private health insurance and private medical care should be in the nature of an alternative method of providing the *entire* coverage which individuals or groups may elect under prescribed conditions, rather than just additional coverage to supplement the basic minimum protection otherwise offered by social insurance. "Supplementary" medical care, carrying on where the compulsory minimum provisions leave off, would surely often complicate matters and unnecessarily harass the

patient by subjecting him to a switch from one system to another, perhaps just at the very time he most needs continuity of treatment. What the effect would be on the quality and effectiveness of the medical treatment is a question for a physician to answer, but I suspect the answer would be far from favorable. When a physician knows that his primary responsibility for a certain case is limited in time or extent, or shared contemporaneously with some other physician or physicians, should we expect his sense of responsibility, of independence, and of initiative in the case, or his personal relationship to the patient, to be keyed to as high a pitch as it otherwise might?

Even if only cash benefits during illness are involved, difficulty arises in dovetailing additional benefits furnished through private channels into a governmental scheme providing the basic minimum. The nature of the risk insured involves relatively greater claim cost than life insurance or annuities, while sound underwriting requires that the total benefits be less than the normal earnings to avoid malingering and abuses. Hence the amount of additional supplementary benefit will often be so low that an excessive part of the premiums for such a benefit will be absorbed in duplicate claim expenses. This difficulty would be avoided if the individual desiring larger benefits than the minimum of the government plan could obtain the entire coverage through an "alternative" arrangement.

(c) *War and Postwar Developments in Medical Care.*—The questions posed are not simply the pros and cons of extending our present social insurance system to health insurance. A number of signs indicate that, irrespective of what the decision is regarding such an extension, the next few years will see a number of major developments and innovations in the provision of medical care. We are told that about one-third of our American doctors and dentists will be in the armed forces by the end of this year. Similar reductions in the civilian supply of nurses and other personnel auxiliary to the medical profession must be expected. Many of us have probably already felt the impact of the resulting changed situation by reason of the accident and sickness of members of our family. Can we safely assume that all of the temporary measures which will be required on account of such shortages will disappear when the war ends? May we not anticipate that experience will show that at least some should be retained permanently?

Then too there will be the exposure of a very large part of the medical profession—especially physicians who have gone from internship to the armed forces—to methods of medical care quite dissimilar in economic and other aspects from the

Case Report

COEXISTENT TYPHOID FEVER AND STAPHYLOCOCCEMIA

FRANK R. MAZZOLA, M.D., F.A.C.P., Jamaica, Long Island, and ARTHUR J. HORTON, M.D., St. Albans, Long Island, New York

THE history of this case is presented with the belief that staphylococcemia coexisting with typhoid fever is very uncommon, a situation made further interesting in this case by the fact that the typhoid fever, which was mild, ran its complete course.

Case Report

The patient, a 17-year-old white boy, was admitted to Mary Immaculate Hospital, Jamaica, Long Island, complaining for four days prior to admission of pain in the right lumbar region and in the right lower quadrant. Three days before his admission, the pain radiated to the right thigh and scrotum. Frequency and urgency, with dysuria, were noted. The pain in the right lumbar region began as a dull ache and increased in intensity until it became stabbing in character. There was no vomiting and no history of injury. One week before his hospitalization the patient had been camping on Long Island. His previous history was one of frequent tonsillitis. Occasional precordial pain was noticed, with palpitation on exertion. No history was obtained of dyspnea or ankle edema. In 1935 the patient had received three injections of typhoid vaccine at the Department of Health, New York City.

On admission to the surgical service, the patient appeared very acutely ill and toxic, with considerable pain, causing him to twist and turn about in bed. The temperature was 103 F. and the pulse 90. Flexion of the neck elicited considerable nuchal pain. The chest was negative. A soft systolic murmur was heard over the apex. The abdomen revealed tenderness in the right lower quadrant but no rigidity. No masses were made out. The liver and spleen were not palpated, but over the right costovertebral angle extreme tenderness was present. It was noted that a partially healed encrusted furuncle was present below the right knee. Urologic consultation was sought by the surgical service, and in turn medical consultation was requested to rule out a meningitis. A blood culture and a flat genitourinary plate were taken. The flat plate was negative. On the day following admission, the patient's temperature rose to 105 F., and the pulse dropped to 86. A leukocyte count, taken on admission, showed 6,700 white cells with 82 per cent polymorphonuclears and 18 per cent lymphocytes. Two days later the count rose to 20,600 with 95 per cent polymorphonuclears. The sedimentation rate was 42 mm. per hour.

The high temperature (now 106 F.) was out of proportion to the pulse rate—104. The pain in the right lumbar region was not so severe, and the patient appeared quite toxic and drowsy. No skin lesions on the abdomen were noted, but the subsiding furuncle below the right knee was still visible. A systolic murmur was heard over the pulmonic

region. The spleen was not palpable. Because of the nuchal pain, a lumbar puncture was done revealing a pressure of 4 mm. of Hg, a clear fluid, a cell count of 1, and a slight reduction to Benedict's solution. A Widal was suggested because of the temperature/pulse ratio and the low white blood count. Stool cultures and blood cultures were also taken. The urine, which had been negative on admission, now showed a 3 plus reaction for albumin, with 4 to 5 white blood cells per high power field.

The blood culture taken two days after admission returned positive for typhoid bacilli, which were also revealed in the stool and urine. The Widal was positive in 1-100 dilution, and two days later became positive in all dilutions. The patient was isolated and placed on a high caloric diet. Meanwhile, the pain in the right lumbar region had become excruciating, and although the tenderness extended to the right loin, right flank, and right upper quadrant, no bulging was noted. X-ray examination revealed no definite outline of the kidney shadows on the right side, and the distended colon covered the psoas muscle line. Rose spots were noted on the abdomen on the sixth day.

For the next three days the condition of the patient remained about the same. He was very toxic and drowsy except when disturbed. A blood culture taken on the eighth day showed no typhoid bacilli, but numerous colonies of *Staphylococcus aureus* and *Staphylococcus albus hemolyticus* were present. On the ninth day fullness in the right flank was noted. The right lumbar space was punctured and aspirated by the G.U. service, but no pus was obtained. Rales were present at the left base with distant breath sounds at the right base. New crops of rose spots continued to appear on the abdomen, persisting for two or three days. Several new pustules were observed on the left arm. Pain began to be present on liver percussion. The temperature varied between 104 F. and 105 F.; with a pulse of from 110 to 120. The white count on the ninth day had risen to 24,800 with 94 per cent polymorphonuclears. It was thought that there was a suppurative process, but its exact site was not determined.

The neck stiffness still persisted, but as a previous spinal fluid examination had been made and was found negative, no further lumbar punctures were done. It was believed at this time that the neck stiffness came from a spasm of the long spinal muscles resulting from an infection in the right flank. A diagnosis of renal carbuncle, as well as typhoid kidney, was considered. Typhoid bacilli were present in both urine and stools on the ninth day.

On the eleventh day following admission, any movement of the patient caused severe pain. The bulging in the right flank was still noticeable, and extreme tenderness continued over this area. The next day, a slight swelling in the region of the thyroid was noted; on the fourteenth day after admission this had become definitely larger, tender, and indurated. The white count rose to 57,000,

From the Third Medical Service, Mary Immaculate Hospital, Jamaica, Long Island.

that field will aid the individual participant in meeting the stormy days ahead.

As to health insurance, there is still much unexplored country to be charted, despite all the discussions that have taken place. Following blindly the precedents of our governmental old-age, survivorship and unemployment insurance plans, or of government plans adopted abroad, is not the route we should take. The broad concept that a social minimum of protection against the hazards of life should be governmentally provided, or at least assured, should not be carried over without modification from our pres-

ent social insurance plans to the field of benefits in kind (medical care) because of the intimate and personal nature of the services that may be required in the latter field. Here the role of the Federal government should be one of greater aloofness, confined to assuring that adequate care will be provided, rather than directly participating in the actual provision. Such direct participation would be appropriate only when no suitable agency appears to be available, and where the choice would seem to lie between a bare minimum governmentally provided, and outright charity or nothing at all.

"DOCTOR JONES" SAYS—

"A dirty business"—that's what a state health official said recently about organized prostitution.

And that just about describes it. The venereal diseases and so on (us health officers—of course that's what we're chiefly interested in)—what makes it a still dirtier business: oftener'n not it's the part that shows of a criminal underworld system.

If the women kept the money they made—anywhere from ten or fifteen to forty or more customers on a busy night, so they claim—you could see how, to a mental defective, it might look for a while at least like a profitable job. But the women, they only get part of the proceeds: a small part of it, sometimes, so I've heard, after they've taken out for board and clothes and drinks and what not. The bulk of it: there's the Madams, of course, to be paid and then there's the "big shot" that runs the whole outfit and the "man higher up" (the man lowest down, if you ask me) that's supposed to see to it that the laws aren't enforced: that the places are protected and the public ain't—and so on. And then, there's the—do you remember that book "The Inside of the Cup"—Winston Churchill? (the American—not the British Churchill). That Minister—you remember he cracked down on a member

of his congregation: the fellow that owned the property where some of these houses were? No, sir. I wouldn't say it's the kind of business any self-respecting community ought to tolerate.

Some of these cities—when the pressure starts for closing up these places, somebody most always gets those old arguments out of cold storage: "It's better to have 'em where the doctors can examine 'em"—"if you clean out the district you'll scatter 'em"—"if you close 'em your daughters won't be safe"—all that junk. If a doctor examined every one of 'em every day it wouldn't prevent 'em spreading disease. If they're scattered and kept moving they can't do much business. Commercialized and segregated prostitution is organized crime. From what I read experience has shown not only that decent women and girls are safer where it don't exist but that when these houses are closed up (by an honest administration) there's less outside prostitution and not more.

Of course there's the problem of treatment and rehabilitation and all that. But as for cleaning 'em out: there's plenty of legal machinery. But they ain't liable to need it if the right fellow says "Git!" and let's 'em know he means it.—Paul B. Brooks, M.D., *Health News*, December 7, 1942

MARKLE FOUNDATION FURTHERS TEACHING OF TROPICAL MEDICINE

The Association of American Medical Colleges has received \$25,000 from the John and Mary R. Markle Foundation for a program to improve instruction in tropical medicine in medical schools in the United States and Canada. Every medical school has been offered an opportunity for two members of its faculty to attend a two-month course.

The development of this program is in charge of a committee on tropical medicine of the Association

of American Medical Colleges. The committee consists of Drs. Henry E. Meleney, Herman M. Biggs, professor of preventive medicine, New York University College of Medicine, chairman; Malcolm H. Soule, Sc.D., professor of bacteriology and head of the department, University of Michigan; and Dr. Hiram W. Kostmayer, acting dean, Louisiana School of Medicine of Tulane University, New Orleans.—*J. Med. Soc. Co. N.Y.*

typhoid dropped to 4.4 per 100,000. In 1918, however, the rate had risen to 30 per 100,000.

Typhoid usually runs a milder course if the disease occurs following prophylaxis. Webb-Johnson reports 3.38 per cent mortality in vaccinated cases, with 7.55 per cent complications, as against 19.19 per cent mortality, with 35.69 per cent complications in unvaccinated cases. Vaughan, in a report

of typhoid in the A.E.F., reports a mortality of 11 per cent in vaccinated cases.

The typhoid fever in this case appeared to follow a true clinical course and seemed to be mild.*

* The authors wish to thank Drs. Erskine and Furey of the Pathology Department of the Mary Immaculate Hospital for their kind cooperation.

CHRONIC EXHAUSTION INCREASING AMONG TEST PILOTS

The discovery of an increased incidence of chronic exhaustion in test pilots as compared with that in transport pilots led Jan H. Tillisch, M.D., and Maurice N. Walsh, M.D., Rochester, Minnesota, to make a study of the condition from which they conclude that several things can be done to prevent this chronic exhaustion state.

They point out that when one considers the nature of a test pilot's work the increased incidence of chronic exhaustion is not surprising.

"We use the term 'chronic exhaustion state' because we do not believe the functional disturbances encountered in a pilot are any different from the functional disturbances encountered in any other high-tensioned person subjected to overwork and prolonged emotional strain. The human nervous system behaves as if it were a storehouse of potential energy. When its store becomes depleted, symptoms of exhaustion make their appearance and if the person is subjected to long-continued mental fatigue, recuperative processes do not have the opportunity fully to restore the nervous energy that has been utilized, so that he is forced to rely on a special reserve store, which may be called the 'nervous energy reserve' and which is intended to be used only for emergencies. . . . In time depletion of this nervous energy reserve occurs, and the manifold symptoms of chronic exhaustion appear. The most common of these symptoms are the following: chronic fatigue, a feeling of inward tension and uneasiness, anxiety, difficulty in concentration, insomnia, irritability, headache, gastrointestinal disturbances, and a generally increased awareness of and a preoccupation with bodily processes. . . ."

The two physicians examined 20 pilots doing test flying and 12 of them were found to be suffering from a chronic exhaustion state. In 4 of the 12 this was of sufficient severity to interfere seriously with their flying an airplane or to stop their flying entirely. All of the 12 pilots suffered from exhaustion, 7 from anxiety, 5 from mental depression, 8 from functional gastrointestinal disturbances, 4 from loss of confidence in flying ability, 3 from insomnia, 5 from irritability, and 2 from headaches. The 4 pilots whose symptoms were sufficiently severe to interfere with their flying were older than the remaining 8 and had been test pilots for a longer period. With a vacation period these 8 pilots returned to normal.

Commenting on their study the two physicians say that "At first thought one may reason that a high incidence of chronic exhaustion is to be expected in all professional aviators. Yet, in a group of 103 transport pilots similarly studied by one of us with an associate there was not a single incident of a

chronic exhaustion state. Therefore, the exhaustion cannot be attributed to flying alone. Nor can we attribute it to high altitude flying alone, as the onset of the exhaustion did not always occur when a man was doing high altitude work. But it did occur with long hours of hard work without vacations and with the emotional strain of flying a new, and at times hazardous, airplane. It is the etiologic (causative) factors that are different; the end result is the same. It must be kept in mind, however, that other factors also can play a part in causing exhaustion in pilots. Aviation, and especially test flying, attract high-strung persons who are more susceptible to functional disturbances than are average men. Social or financial maladjustment is a prolific cause of chronic fatigue. A pilot, as he gets older, worries about his physical fitness for carrying on his work, and this again may be a source of functional disturbances.

"Several things can be done to prevent this chronic exhaustion state. Good physical condition should be assured by frequent medical examinations and correction of defects. At least eight hours of sleep a night should be obtained. A pilot should keep himself in good physical condition by regular exercise. . . . All pilots who fly high-powered machines and operate at high altitudes, as do test pilots, should have frequent rest periods. For test pilots a rest of at least one week in each seven is recommended. In our experience frequent short vacations have been of much greater value to a pilot than infrequent long vacations. The importance of hobbies in securing mental relaxation should be emphasized, and a pilot should be encouraged to cultivate some. The most satisfactory hobbies are those which are not related to one's everyday occupation and which involve making something with the hands or forming collections. The indiscriminate use of sedative agents by pilots in an effort to dissipate nervous tension cannot be condemned too strongly. A sedative should be taken only when it is prescribed by a physician. The continued use of stimulants, such as alcohol or amphetamine sulfate, is dangerous, as either one may lead to errors of judgment.

"The time taken to train a test pilot and his important role in the development and production of modern airplanes make it paramount that this group of men be maintained in the best of physical and mental condition. Because test pilots undergo the physical and emotional stresses compressed into a short period to which the entire pilot profession is subjected over a longer period, study of this small group may yield a greater insight into the problems of the entire profession."—A.M.A. News

with 95 per cent polynuclears. Acute suppurative thyroiditis was considered and was confirmed by both surgical and otolaryngologic services. Dyspnea was not very marked. A transfusion of 500 cc. of citrated blood was given. Treatment with bacteriophage prepared from the organisms secured from the blood culture was begun.

On the fourteenth day, the patient appeared more toxic. Petechiae were noted in the right conjunctiva.

The thyroid swelling was slightly larger and showed definite fluctuation. The pulse rate rose to 120, and an apical systolic murmur was heard. An endocarditis was considered at this time. Posteriorly, rales were heard in both lungs, particularly at the left base. A patch of bronchial breathing was heard over this area also. The tenderness in the right lumbar region was somewhat diminished. A small mass was palpated in the right lateral epigastric region, but because of the critical condition of the patient, exploration of the same was not carried out.

Urologic consultation at this time stated that no evidence of perinephritic infection was present. The white count was 51,700 with 94 per cent polynuclears, and the red count was 3,750,000 with 74 per cent hemoglobin. Many toxic granules were noted in the smear.

On the fifteenth day the patient became extremely toxic; the respiratory rate was 66, and the pulse rate was 168. Coarse moist rales were heard throughout the chest. His condition remained critical throughout the day. Early the next morning he became comatose, was in pulmonary edema, and had a temperature of 107 F., expiring at 11:30 A.M.

Postexamination

An extensive uniform bulging of the neck was noted in the region of the thyroid. Both lobes of the thyroid were enlarged, and most of the thyroid tissue had been replaced by a homogenous yellow inspissated material.

Thin fluid was present in the left pleural cavity. Patches of thin filmy adhesions were found over small nodular swellings scattered over the lung surfaces. An abscess cavity extending from the twelfth thoracic to the second lumbar vertebra was discovered when the medial lumbocostal arches of the diaphragm were freed, destroying partially the body of the first lumbar vertebra. In addition, the first portion of the psoas major muscle and its fascia were destroyed. Thick yellow pus was present in the cavity and also in the right azygos vein.

When the heart was examined, a patent foramen ovale with friable brownish vegetations on both sides of the septal opening was discovered. On the right cusp of the mitral valve a vegetation of the same character, 3 mm. in diameter, was present.

Nodular areas, yellowish to deep red in color, and from 1 to 3 mm. in diameter, were scattered over the surfaces of both lungs. Small abscess cavities filled with thick, yellow pus were found deep in the lung parenchyma.

In the region of the terminal ileum two areas, each 12 mm. in length, revealed marked mucosal hemorrhage and hyperemia. The Peyer's patches were not remarkable. The spleen was very soft, being a yellowish white color over its superior and

medial aspects. Both kidneys were enlarged and soft; yellowish nodules containing thick yellowish pus were present in both cortex and medulla. A small prostatic abscess was present, as well as an enlarged and purulent right epididymis. A healed, crusted lesion measuring 1 cm. in diameter was noted just below the right knee.

Postmortem bacteriologic examination revealed *Staphylococcus aureus* and *albus hemolyticus* in the heart blood; *B. coli* were also present in the abdominal pus. The free pus in the abscess cavity was positive for *Staph. aureus hemolyticus*.

Microscopically, most of the thyroid tissue was necrotic; infiltrated with plasma cells and mononuclears.

A triangular area of lung infarction was discovered in the right lower lobe with old hemorrhagic elements, edema, and dense infiltration with pus cells and staphylococci groups.

Section of the interauricular septal defect revealed a fibrinous exudate on the endocardium of the right auricle densely infiltrated with pus cells. These pus cells extended through the endocardium and into the muscularis for a short distance. The myofibrils showed granular degeneration and a brownish pigment at the nuclear poles.

Kidney tissue revealed several small areas of metastatic abscess in both cortex and medulla. Sections of prostate, testes, and epididymis were similar. Azygos vein sections near the region of the paravertebral abscess noted fibrinous necrotic material replacing the intima.

The ileum showed areas in which the surface was denuded, with considerable remaining glandular epithelium. There were no areas of Peyer's patches. Vascularity of the mucosa was increased, and there was free hemorrhage into the mucosa and on the surface.

Final Pathologic Diagnosis

1. Staphylococcemia with multiple abscesses in kidneys, lungs, paravertebral region, prostate, epididymis, testes, and thyroid.
2. Endocarditis (vegetative).
3. Splenitis—acute.
4. Granular degeneration of liver.
5. Typhoid fever (third week).
6. Myocardial degeneration.
7. Suppurative phlebitis azygos vein.

Conclusion

Late complications of typhoid fever are of common occurrence in the literature, but reports of practical coexistence of typhoid fever and staphylococcemia are almost unavailable. It is felt in the above reported case that the lowering of the patient's resistance by the typhoid infection apparently precipitated the staphylococcemia.

The occurrence of typhoid fever following typhoid prophylaxis is rare; Cook, in the *Naval Medical Bulletin*, reports a total of 895,680 inoculations given, with only 75 cases being reported from 1924 to 1933. In the U.S. Army following compulsory inoculation in 1912, the rate of cases developing

from England, describe more than a year of service in the Emergency Medical Service of the British Ministry of Health. The society discussed plans for establishing an emergency fund for the benefit of families of doctors killed or injured in service and also approved appointment of committees to discuss gas rationing with officials of the Broome County Price and Rationing Board and to study the narcotics and drug addict problem.

Dr. Warner, daughter of Mr. and Mrs. Frank E. Warner, of Binghamton, told of conditions in English hospitals which became so acute during enemy bombings that in some institutions it was necessary to place three and four patients in a bed.

She served on the staffs of several hospitals during her stay in England. In the Royal Southern Hospital in Liverpool, she said, many of the beds consisted of iron cots with straw mattresses, heating was inadequate, and the staff worked nightly with very little light.*

Dutchess County

Dr. Emil L. Stoller, of Poughkeepsie, was elected president of the county society at its annual meeting at the Hudson River State Hospital on January 13. He succeeds Dr. Edgar F. Powell, of Fishkill.

Other officers elected for the year were: Dr. Harry A. LaBurt, superintendent of the Harlem Valley State Hospital, vice-president; Dr. Albert A. Rosenberg, of Poughkeepsie, secretary-treasurer; Dr. Joseph L. Cummings, associate secretary; censors, Drs. Alva L. Peckham, Howard P. Carpenter, Gilbert S. Tabor, L. Edward Cotter, and Julius Haight; delegate for two years, Dr. Scott Lord Smith, with Dr. Samuel E. Appel holding over as a delegate; alternate delegate for two years, Dr. Chester O. Davison, with Dr. Aaron Sobel holding over; counselor, Dr. Leonard K. Supple.

Dr. Rosenberg succeeded Dr. John F. Rogers, now a major in the U.S. Army Medical Corps, as secretary-treasurer. Dr. Carpenter, who held the post over a long period prior to Dr. Rogers' election, had been serving temporarily in the post.

The scientific paper was given by Dr. Joseph S. Lawrence, executive officer of the State Medical Society, who spoke on the "Family Physician of Tomorrow."

Dr. Stoller has practiced in Poughkeepsie since 1926. He is at present an assistant surgeon on the staffs of Vassar Hospital and the Hudson River State Hospital.*

Greene County

A meeting of the county society was held at Memorial Hospital on January 12 at 9:00 p.m. Matters of interest to physicians of the county were discussed.*

Jefferson County

The regular monthly meeting of the county society was held on January 8 at the Black River Valley Club, following dinner at 6:30 p.m.

Four-minute addresses were given by members of the society.

The four-minute speakers and the topics of their addresses were: Dr. H. N. Cooper, "Pressure Treatment of Burns"; Dr. D. G. Gregor, "Advance in the Treatment of Carcinoma of the Prostate"; Dr. N. L. Hawkins, "Active Immunization Against Tetanus"; Dr. W. W. Hall, "Dicoumarin, a New Drug"; Dr. Garner Scullard, "Use of Serum in

Influenza Meningitis"; and Dr. G. S. Nellis, "Industrial Hygiene."*

Kings County

Physical examinations for men drafted into the armed services, heretofore, in many cases, given in the homes and offices of Brooklyn physicians, are now being taken by large numbers of registrants in hospitals and dispensaries throughout the borough, according to Col. Samuel J. Kopetzky, chief of the medical division of the New York City Selective Service System.

Colonel Kopetzky disclosed that the transfer in Brooklyn is part of a city-wide plan to move all examinations from draft board headquarters and the homes and offices of private doctors to hospitals, where better facilities, volunteer nurses, free light and heat, and volunteer clerical help are available.*

The second annual president's dinner of the Medical Society of the County of Kings was held in the Waldorf-Astoria on January 28. Dr. Charles F. McCarty was chairman of the dinner committee.

Dr. William C. Meagher, retiring president, was presented with a medal and scroll by Dr. George W. Cottis, president of the Medical Society of the State of New York.*

Nassau County

Five Nassau doctors will serve on the advisory medical board of the Adelphi College School of Nursing.

The first class of the new institution, one of seven established throughout the state as New York's contribution to the war-emergency nurse-training program, opened on the Garden City campus on February 1.

The medical board, nominated by the Nassau County Medical Society and appointed by the college trustees, are: Dr. Benjamin W. Seaman, chairman, a director of Meadowbrook General Hospital, head of the surgical staffs of Nassau Hospital, and North Country Community Hospital, and a former president of the medical society; Dr. Everett N. Whitcomb, of Port Washington, president of the medical society; Dr. Louis H. Bauer, of Hempstead, speaker of the House of Delegates of the State Medical Society; Dr. Arthur C. Martin, of Hempstead, twice president of the medical society; and Dr. Louis A. Van Kleeck, of Manhasset, former president of the society.*

Tribute was paid to the founders of the Manhasset Health Center by Dr. L. A. Van Kleeck, one of the speakers at a luncheon on January 18 at Plandome Gardens, which marked the twenty-fifth anniversary of the organization. Among the guests were Mrs. Charles M. Niesley, widow of the founder of the Health Center, and several past presidents. Mrs. A. O. Eldridge presided.*

During 1942 Nassau County recorded 6,874 cases of infectious diseases, 8,658 cases fewer than were reported for the year 1941.*

New York County

The interesting report which appears below came to us following the testimonial dinner given to Dr.

* Asterisk indicates that item is from local newspaper.

Medical News

Painless Childbirth Claimed for New Technic

COMFORTABLE and painless childbirth, which is safe for both mother and child, is claimed for the new "continuous caudal analgesia" technic recently developed by Dr. Robert A. Hingson and Dr. Waldo B. Edwards, officers of the United States Public Health Service, who are stationed at the Marine Hospital at Stapleton, Staten Island.

However, both the physicians who developed it and the *J.A.M.A.* cautioned that the method should be used only in hospitals and only by doctors specially trained in this particular technic, and that there are certain types of cases in which it should not be used.

Physicians who have used it described it "as the best method yet devised," "100 per cent effective," "perfect painless childbirth," and apparently "the last word in obstetric analgesia."

The new method has been in use less than a year. It involves injection of a solution of metycaine, a cocaine substitute, into the cauda, which is at the lower tip of the spine. A special apparatus devised by the physicians is used and the injections are given

every thirty or forty minutes throughout the entire course of labor.

The pain-killing drug bathes the nerves at the end of the spine, but does not enter the membranes covering the spinal canal, with the result that the anesthesia does not cause loss of consciousness or hinder muscular movements which have a part in voluntary delivery of the baby.

The method was first used at Staten Island on January 6, 1942, and since then has been tried in nineteen clinics associated with medical schools and well-established hospitals.

"Altogether some 589 women have been delivered of babies by this method without maternal mortality and with but three instances in which infants died—these without reference to the method of analgesia that was employed," the *J.A.M.A.* said.

The journal, commenting that relief of childbirth pain has been one of the medical profession's long-sought goals, termed the method "a real advance" and published comments from other physicians who have tried it.

Planned Parenthood Federation Gets \$50,000 Gift

TO HELP us win the war by curbing illness among women war workers, Albert D. Lasker, retired advertising executive and former chairman of the United States Shipping Board, has given \$50,000 to the Planned Parenthood Federation of America, Inc.

The gift is the largest single contribution ever made to the 21-year-old organization and marks the opening of a drive by the federation for \$289,693 "to carry forward a health and public education program which contributes directly to America's war effort."

When he turned over a check for \$50,000 to Richard N. Pierson, president of the federation, Mr. Lasker discussed his reasons for the gift.

"A race that is vigorous, healthy, happy, and self-reliant is the real hope of democracy and lasting peace," he said. "It is my conviction that once planned parenthood is made a part of our public health and welfare services, more healthy children will be born to maintain the kind of peace for which we are fighting."

"Through its national program, the Planned Parenthood Federation of America can make clear the importance to the immediate and future well-

being of the country of child-spacing.

"I have always been a firm believer in the ability of democratic men and women to discern for themselves the truth—once the facts have been made available. At present, child-spacing information is still too largely available only to the privileged few, and not the great majority which numbers among it those who need the information most."

"Planned parenthood has made great strides in the past. Leaders in federal, state, and county health programs now recognize its importance to any health program. The medical profession also is beginning to recognize its importance to the whole field of preventive medicine. The objectives are now plainly in view—but there remains much concentration of time, energy, and effort before they can be reached."

Mrs. Lasker, who is secretary and a member of the board of directors of the federation, emphasized her husband's words by pointing out that production in some of the largest war plants had been seriously hindered by ill health among women workers. In one of the largest plants, she said, the abortion rate among women, on the basis of reported cases only, had jumped to 27 per 1,000 women workers.

County News

A list of the officers of all of the county societies appears on page 378.—Editor

Albany County

A meeting of the county society was held on January 27 in the Albany College of Pharmacy at 8:30 P.M.

The scientific session featured an address on "Suppurative Diseases of the Chest" by Adrian A. Ehler, M.D., of Albany, which was followed by general discussion.

Allegany County

Dr. L. S. Benedict, of Wellsville, has been named a director of the county laboratory, to succeed the late Dr. F. E. McCarty.

Broome County

Members of the county society on January 12 heard Dr. Florence Warner, who returned recently

ress that is being made in the fight against pneumonia, the reporting of this disease to the Department is now feasible and necessary."

. . .

The following physicians were elected officers of the New York Physical Therapy Society for the ensuing year at the meeting held on January 6: president, Harold Neifeld; vice-president, Charles G. Buckmaster; treasurer, Richard Kovacs; secretary, Madge C. L. McGuinness; executive committee, Stella S. Bradford, Karl Harpuder, Michael J. O'Conner, Jerome Weiss, and Lewis J. G. Silvers, chairman.

. . .

The New York Chapter of the American Red Cross needs 7,500 pints of blood weekly, an increase of 2,500 pints over its previous quota, to meet the total national requirement of 4,000,000 pints in 1943. Col. Earle Boothe, director of the blood-donor service of the chapter, announced recently.

Colonel Boothe said that this would involve the reception of 100 persons an hour through a nine-hour day in the center, with the rest of the chapter's quota being supplied by mobile units which collect blood in the suburban area.*

. . .

Control of disease on a world-wide scale is a necessary part of the postwar program, Dr. J. Stanley Kenney said on January 25 in his inaugural address as president of the Medical Society of the County of New York at the New York Academy of Medicine.

Dr. Kenney stated that many areas of the world have been lacking in disease prevention and public health methods—areas which today are being entered by members of the United States armed forces.

"Because of the rapid modes of transportation and the constant interchange of peoples," he said, "we are no longer isolated, and those pestilential diseases that are endemic in those far-away places might become a real concern here at home."

During his tenure of office he said the society would keep itself informed and weigh carefully various proposals for postwar settlement.

But Dr. Kenney also pointed out the need for a health rehabilitation program in the United States. "Statistics published during the last year and a half as a result of selective service," he said, "have aroused the nation out of its complacency. More medical care is needed to improve and correct many of the defects and diseases which examination reports have brought to light."

"The labor shortage and demands for workers in essential war industries reveal the tremendous need for a rehabilitation program in this field. In the near future a national program will have to be promulgated."

The society will promote the acceptance by the public of medical expense insurance, Dr. Kenney said, using its influence and authority to put it into successful operation in New York County. "Adequate medical care must be furnished the public at a cost they can afford, and this cost must be spread over large groups to reduce the expense to the individual patient," he said.

Dr. Maximilian A. Ramirez is the retiring president of the county society.*

. . .

The marriage of Dr. Barbara Ann Parker, daughter of Mrs. Florence Van Wagenen Parker, of Oxford, New York, and the late Charles Joel Parker, to Dr. Herbert Chasis, son of Mrs. Anna Kutner Chasis, of New York City, and the late Dr. Joel M. Chasis, took place on January 19 in the Ambassador Hotel.

Mrs. Chasis was graduated from Vassar College and New York University College of Medicine and is now interning at Bellevue Hospital. Her husband was graduated from Syracuse University and New York University College of Medicine, where he is assistant professor of medicine.*

Oneida County

Foster Kennedy, M.D., delivered the first lecture in a postgraduate course on war medicine and surgery for the Oneida County Medical Society in Utica, under the auspices of the State Medical Society and the State Department of Health. He spoke on January 26, on "Nervous Conditions Associated with Warfare."

"General Principles of Treatment of War Injuries," by Dr. Philip Duncan Wilson, clinical professor of orthopaedic surgery, College of Physicians and Surgeons, was the second lecture in the series.

The third lecture, on February 9, was entitled "The Care of Soft Tissue Injuries." Dr. Forrest Young, assistant professor of surgery, University of Rochester School of Medicine and Dentistry, was the speaker.

On February 16, "Epidemiology and Control of Syphilis" will be discussed by Dr. James H. Lade, assistant director, division of syphilis control, State Department of Health. Dr. Lade's talk will be supplemented by a technicolor sound film, provided by the state health department.

. . .

The Utica Academy of Medicine closed the year 1942 with a regular monthly meeting at Hotel Utica on December 17. Lt. Col. Irwin Alper of the Rome Air Depot was the guest speaker. He is a flight surgeon, and the subject of his talk was "Physical Examination for Fliers."

Onondaga County

"Nutrition and Cancer" was the subject of a lecture by Dr. Cornelius Rhoads, director of Memorial Hospital for treatment of cancer and allied diseases in New York City, on January 7 in the auditorium of the College of Medicine, Syracuse University. The audience was composed of Syracuse doctors and students in the College of Medicine and College of Home Economics.*

Oswego County

Dr. William Fivaz, of Fulton, was elected president of the county society at the annual meeting held in the Fortnightly Club in January. He succeeds Dr. John F. Burden, of Oswego.

Other officers are: Dr. Harold J. LaTulip, Oswego, vice-president; Dr. Harold F. McGovern, of Fulton, secretary-treasurer; Dr. Harrison M. Wallace, censor for three years; Dr. Olin Mowry, of Minetto, member of the legislative committee; and Dr. K. Wood Jarvis, member of the public relations committee.*

Queens County

A stated meeting of the county society was held on January 26. Dr. Virgil H. Moon, professor of

A. Bern Hirsh, who has just retired as managing editor of the *County Journal*:

Recognition of many years' service for the profession and the public marked the testimonial dinner given Dr. A. Bern Hirsh on Thursday evening, January 28, at Hotel Savoy-Plaza, by New York City medical and other leaders. Dr. Chas. Gordon Heyd was toastmaster and various speakers dwelt on the many-sided activities so long rendered the community by the evening's guest. Among these was Col. Samuel J. Kopetzky, medical chief of the Assignment and Selective Service of the metropolitan area, who told of his twenty years' association with Dr. Hirsh as coeditor of *The New York Medical Week*, of which official organ they were the founders, the title of which had been changed a year ago to *Journal of the Medical Society of the County of New York*.

When called on for some concluding remarks, he described how the important county society "Branch" system and its official periodical, now spread over the country from coast to coast, had their origin in Philadelphia early in this century, where he was at that time practicing his profession. Joining with those who were interested in the annually recurring effort to win better state medical laws, he was brought into touch with fellow practitioners in the more distant parts of the city. He was impressed by the occasional remark—explaining the seeming indifference of some of these men to join—that they had so little to show for membership in the county society as then conducted; that no opportunity existed to greet fellow members regularly socially or to listen with them to a scientific meeting program.

This was largely because, in the residential part of a large city, the average family physician must hold late evening office hours, his clientele being at business during the daytime. Again, as the hall of the county society was located in midtown, distance alone prevented attendance by doctors living in outlying areas. It was not surprising, then, that their enforced isolation and unintentional neglect by the society should have caused indifference, if not, at times, actual resentment.

The complaint was amply warranted and the situation was one of bringing the mountain to Mahomet—of organizing local meeting centers as affiliates of the county medical society. This seemed to be the logical answer. It was in meeting this demand that the "Branch" system had its birth, and its popularity was assured as the plan was taken up later by other population centers. The aim was to afford regular meetings, at least monthly, for physicians in the branch district, at which formal scientific programs could be presented.

An ardent coworker at the time was the late Dr. Albert M. Eaton, afterward a president of the county medical society. Praise is due his memory for the many hours he contributed and long journeys he helped Dr. Hirsh to make evenings, after busy days with patients, in founding these branches. Five years' spare hours were devoted to this campaign. Two of the branches were in active operation within the first year of the new century and ultimately seven such centers were found necessary to serve the city's profession.

Some means for more regular communication with the society's members—affording better publicity for the movement—seemed wanting at the outset. It was then that it occurred to the speaker that more rapid progress would be possible in multiplying these branches if the Philadelphia County Medical Society, jointly with other local medical organizations, were to issue a printed bulletin each Saturday containing their prospective meeting programs along with brief news notes on local medical occurrences. It was this proposal that initiated the county medical society periodical, now found in so many centers from coast to coast. Active agitation for its adoption was carried on in medical societies at the outset, although the suggestion did not at first find favor. Mention of the plan did, however, appear in medical

journals about 1901, both about the founding of the branch system and that of the proposed weekly organ.

Chicago, in 1902, and Philadelphia, in 1905, were the first to issue such a publication.

Dr. Hirsh cited a few facts that supplemented the account that had been given by Colonel Kopetzky of the origin of *The New York Medical Week*. An old Philadelphia acquaintance, the late Dr. Richard Pearce, of the medical faculty of the University of Pennsylvania and later a trustee of the Rockefeller Foundation, had learned in 1917 of Dr. Hirsh's intended resignation as editor of the Philadelphia *Roster*, prior to his moving to New York. He suggested the starting of a similar weekly in the metropolis and advised consulting Drs. L. Emmet Holt and J. Bently Squire concerning this. These leaders, when interviewed, told him that they favored the idea but, with the country involved in World War I, they thought it would be best to defer its initiation until the return of peace.

Ending his army service in 1920, Dr. Hirsh sometime later called on Colonel Kopetzky and offered suggestions for the proposed publication, details being finally worked out. Under typical energetic leadership by the latter, medical New York at length had its weekly paper, its circulation in time reaching 7,200, with a country-wide distribution and its contents frequently quoted. It was a smoothly running editorial group who functioned in perfect harmony, week in and week out, for twenty years—Kopetzky guiding the paper's policy and outlining his constructive editorials; Miss Kaplan checking source material to assure accuracy of contents and, in her terse English, writing the editorial page as indicated; the speaker, as news and managing editor, among other duties, gradually influencing some fifty medical organizations to insert their news and meeting programs in this union medium.

Dr. Hirsh, in conclusion, briefly referred to the many favorable results that followed founding of such papers, their very multiplication being the best proof of their usefulness to the profession and the public in general.

The Board of Health has added keratoconjunctivitis and virus pneumonia, more properly termed "primary atypical pneumonia," to the list of communicable diseases required to be reported to the Department of Health.

In New York City, reports coming to the Health Department from practicing physicians indicate that primary atypical pneumonia is being encountered rather extensively in this area. Reporting of the disease should give the Department a closer check on the extent of the pneumonia problem in this city.

"The Board's action," said Dr. Ernest L. Stebbins, commissioner of health, "should not be taken as indicating that pneumonia is on the increase. As a matter of fact, our recent annual summary report reviewing health conditions in this city in the year just closed showed that extremely gratifying progress continued during 1942 in the fight against pneumonia. Only ten years ago, 7,827 deaths due to pneumonia were registered in the City, a rate of 111 per 100,000 of population. During 1942, there were only 2,959 deaths from pneumonia, a rate of 39.1 per 100,000. This excellent showing must be credited to the widespread use of specific therapeutic serums and the introduction of the sulfonamide drugs in the treatment of this disease.

"Virus pneumonia, which now becomes reportable along with the more familiar and serious communicable diseases such as diphtheria, smallpox, syphilis, tuberculosis, and typhoid fever, is a clinically mild form with a very low death rate. However, the Board of Health felt that in view of the general prog-

ress that is being made in the fight against pneumonia, the reporting of this disease to the Department is now feasible and necessary."

The following physicians were elected officers of the New York Physical Therapy Society for the ensuing year at the meeting held on January 6: president, Harold Neifeld; vice-president, Charles G. Buckmaster; treasurer, Richard Kovacs; secretary, Madge C. L. McGuinness; executive committee, Stella S. Bradford, Karl Harpuder, Michael J. O'Conner, Jerome Weiss, and Lewis J. G. Silvers, chairman.

The New York Chapter of the American Red Cross needs 7,500 pints of blood weekly, an increase of 2,500 pints over its previous quota, to meet the total national requirement of 4,000,000 pints in 1943. Col. Earle Boothe, director of the blood-donor service of the chapter, announced recently.

Colonel Boothe said that this would involve the reception of 100 persons an hour through a nine-hour day in the center, with the rest of the chapter's quota being supplied by mobile units which collect blood in the suburban area.*

Control of disease on a world-wide scale is a necessary part of the postwar program, Dr. J. Stanley Kenney said on January 25 in his inaugural address as president of the Medical Society of the County of New York at the New York Academy of Medicine.

Dr. Kenney stated that many areas of the world have been lacking in disease prevention and public health methods—areas which today are being entered by members of the United States armed forces.

"Because of the rapid modes of transportation and the constant interchange of peoples," he said, "we are no longer isolated, and those pestilential diseases that are endemic in those far-away places might become a real concern here at home."

During his tenure of office he said the society would keep itself informed and weigh carefully various proposals for postwar settlement.

But Dr. Kenney also pointed out the need for a health rehabilitation program in the United States. "Statistics published during the last year and a half as a result of selective service," he said, "have aroused the nation out of its complacency. More medical care is needed to improve and correct many of the defects and diseases which examination reports have brought to light."

"The labor shortage and demands for workers in essential war industries reveal the tremendous need for a rehabilitation program in this field. In the near future a national program will have to be promulgated."

The society will promote the acceptance by the public of medical expense insurance, Dr. Kenney said, using its influence and authority to put it into successful operation in New York County. "Adequate medical care must be furnished the public at a cost they can afford, and this cost must be spread over large groups to reduce the expense to the individual patient," he said.

Dr. Maximilian A. Ramirez is the retiring president of the county society.*

The marriage of Dr. Barbara Ann Parker, daughter of Mrs. Florence Van Wagenen Parker, of Oxford, New York, and the late Charles Joel Parker, to Dr. Herbert Chasis, son of Mrs. Anna Kutner Chasis, of New York City, and the late Dr. Joel M. Chasis, took place on January 19 in the Ambassador Hotel.

Mrs. Chasis was graduated from Vassar College and New York University College of Medicine and is now interning at Bellevue Hospital. Her husband was graduated from Syracuse University and New York University College of Medicine, where he is assistant professor of medicine.*

Oneida County

Foster Kennedy, M.D., delivered the first lecture in a postgraduate course on war medicine and surgery for the Oneida County Medical Society in Utica, under the auspices of the State Medical Society and the State Department of Health. He spoke on January 26, on "Nervous Conditions Associated with Warfare."

"General Principles of Treatment of War Injuries," by Dr. Philip Duncan Wilson, clinical professor of orthopaedic surgery, College of Physicians and Surgeons, was the second lecture in the series.

The third lecture, on February 9, was entitled "The Care of Soft Tissue Injuries." Dr. Forrest Young, assistant professor of surgery, University of Rochester School of Medicine and Dentistry, was the speaker.

On February 16, "Epidemiology and Control of Syphilis" will be discussed by Dr. James H. Lade, assistant director, division of syphilis control, State Department of Health. Dr. Lade's talk will be supplemented by a technicolor sound film, provided by the state health department.

The Utica Academy of Medicine closed the year 1942 with a regular monthly meeting at Hotel Utica on December 17. Lt. Col. Irwin Alper of the Rome Air Depot was the guest speaker. He is a flight surgeon, and the subject of his talk was "Physical Examination for Fliers."

Onondaga County

"Nutrition and Cancer" was the subject of a lecture by Dr. Cornelius Rhoads, director of Memorial Hospital for treatment of cancer and allied diseases in New York City, on January 7 in the auditorium of the College of Medicine, Syracuse University. The audience was composed of Syracuse doctors and students in the College of Medicine and College of Home Economics.*

Oswego County

Dr. William Fivaz, of Fulton, was elected president of the county society at the annual meeting held in the Fortnightly Club in January. He succeeds Dr. John F. Burden, of Oswego.

Other officers are: Dr. Harold J. LaTulip, Oswego, vice-president; Dr. Harold F. McGovern, of Fulton, secretary-treasurer; Dr. Harrison M. Wallace, censor for three years; Dr. Olin Mowry, of Minetto, member of the legislative committee; and Dr. K. Wood Jarvis, member of the public relations committee.*

Queens County

A stated meeting of the county society was held on January 26. Dr. Virgil H. Moon, professor of

pathology at Jefferson Medical College, spoke on "The Prevention and Practical Management of Shock."

A discussion of gasoline rationing for Queens County was given by Mr. James Lundy, OPA chairman for Queens.

. . .

The Friday afternoon talk on February 19 will be "Treatment of Varicose Veins," by Dr. Gerald H. Pratt, associate surgeon and chief of vascular surgery, New York Post-Graduate Hospital Out-patient Department.

Richmond County

Dr. H. Lynn Halbert, of Grymes Hill, conducted his first meeting as president of the Richmond County Medical Society on February 10 in the Richmond Health Center, St. George.

The other physicians who will serve on Dr. Halbert's staff of directors are Dr. D. V. Catalano, vice-president; Dr. Herman Friedel, secretary; Dr. C. J. Becker, treasurer, Dr. Milton S. Lloyd and Dr. S. C. Pettit, delegates to the convention of the New York State Medical Society; Dr. O. M. Race and Dr. E. C. McCulloch, alternates, Dr. Andrew J. McGowan, Dr. Nathanael Fedde, and Dr. Friedel, censors; Dr. F. T. Donovan, delegate to the First District Branch; Dr. C. J. DiCrocco, alternate; Dr. Donald E. Law, member-at-large.*

Saratoga County

A meeting of the county society was held on January 29 at the Saratoga Hospital.

This was the first meeting to be presided over by the 1943 president, Dr. Mark D. Duby, of Schuylerville.*

Westchester County

The county society opened its 1943 program of postgraduate education with an address by Dr.

Cornelius P. Rhoads, director of the Memorial Hospital in New York City, on "Nutrition and Cancer," at a regular meeting of the society held at the New York Hospital, Westchester Division, in White Plains on January 19.

Dr. George C. Adie, of New Rochelle, presided at the meeting, and Dr. Rhoads was introduced by Dr. Gilbert Dalldorf of Grasslands Hospital, chairman of the society's scientific committee.

In the business session preceding Dr. Rhoads' talk, the society adopted a resolution reducing the number of its regular meetings for 1943 to five, and, thereafter, for the duration of the war, to four meetings annually.

In order to insure prompt and adequate response to emergency calls for medical service, the society adopted a report of its executive committee that local hospital staffs be urged to study the need for special services in their own communities and to take whatever steps may be indicated locally to assure prompt coverage of emergency medical calls.*

Wyoming County

Dr. Mary T. Greene entertained the members of the Wyoming County Medical Society and the Wyoming County Community Hospital staff at the Castile Sanitarium on January 13. An invitation was also extended to each member's wife. Following a delicious luncheon, a joint meeting of the two societies was held. Moving pictures of the treatment of varicose veins were shown during the meeting.

The custom of holding an annual meeting at the Castile Sanitarium has been carried on for about fifty-six years, having been originated by Dr. Cordelia Greene, an aunt of Dr. Mary Greene. Dr. Mary Greene has graciously carried on this custom throughout her years as head of the sanitarium.*

Hospital News

Homer Folks Speaks at 100th Anniversary of Utica Hospital

PREVENTION is the "white hope" of reducing the volume and cost of mental disorders, Homer Folks, secretary of the State Charities Aid Association and chairman of the Temporary Commission on State Hospital Problems, declared in an address at the observance of the 100th anniversary of the opening of the Utica State Hospital on January 16.

He said that the State, with a \$40,000,000 annual budget for mental hygiene institutions, is making "one of its worst financial errors" in not pushing a preventive program. He declared that many millions a year in construction and maintenance costs could be saved thereby.

Speaking on "The Tyranny of the Past and the Hope of the Future," Mr. Folks advocated a double offensive to diminish insanity and the cost of caring for its victims. He urged centering one attack on more thoroughgoing and effective treatment of the mentally sick in the hospitals, with the extension of shock therapy and parole and family care, and the other on prevention by means of earlier discovery and treatment through clinics or health centers.

He believes that the time has come for the State "to begin to make good, and in a big way," in

attaining a prevention objective set thirty years ago but not yet realized because it "thought itself unable to afford to carry on an effective system of diagnosis and treatment through clinics."

Mr. Folks recommended that the State hospitals be made more fully hospitals in fact as well as in name, and that searching psychiatric examination of patients should select more patients suitable for parole and family care. He declared that while more and more fully trained psychiatrists in the hospitals, new modes of treatment, and a better understanding of environmental factors in causation are important, prevention is a "white hope beside which all three put together are relatively unimportant."

The Temporary Commission on State Hospital Problems, which is headed by Mr. Folks, recently submitted a progress report to Governor Lehman on a two-year study which had resulted in measures that not only halted the rate of increase in the number of patients in residence in the civil State hospitals for the insane, but brought about an actual decrease in the patient population for the first time in fifty years.

Hospital Standards High Despite Curbs

DESPITE depleted staffs, curtailed supplies, increased expenses, and heavy demands for service, hospitals of the United States and Canada are as a whole maintaining high standards, Dr. Irvin Abell, of Louisville, chairman of the board of regents of the American College of Surgeons, said in announcing that the twenty-fifth annual list of hospitals approved by the organization includes 2,989 institutions, an increase of 116 over 1941.

"The 1942 survey disclosed that a few hospitals previously approved are not meeting the minimum standard today," Dr. Abell said. "Consequently, approval was withheld or a provisional rating given."

"These wartime casualties are more than balanced by the earning of approval by some hospitals which have improved since the last survey. Nevertheless, great shifts of population due to new and relocated

war industries, and establishment of large military encampments, have caused excessive demands for hospital service in some communities, and there is increasing danger of lowered standards in the effort to care for more patients than the depleted staffs can properly serve.

"In this emergency most communities are rallying to the support of the hospitals, furnishing volunteer nurses' aids and other voluntary workers, encouraging study and practice of home nursing, discouraging hospitalization for minor illnesses, interesting young people in careers in medicine and nursing, and increasing disease and accident-prevention efforts. By voluntarily granting hospitalization priorities to the more seriously ill, the people will conserve hospital resources as they are conserving other services and many commodities through allocation according to needs."

Conservation in the Hospital

IN AN article entitled "Conservation Depends on Cooperation," in *The Modern Hospital* for January, Elizabeth Bahrenburg, R.N., assistant director of nursing at the University Hospitals, Cleveland, tells what has been accomplished by a campaign to conserve hospital materials. We quote:

Women's and children's clubs throughout the city are supplying us with bags made of newspapers, replacing the kraft paper bags for bedside use.

A bottle and ointment jar salvage campaign is continuing to be of great help to us. All containers are delabeled and scrubbed before being brought to the pharmacy. They serve numerous purposes, as follows:

1. Ointment jars for pharmacy use.
2. Gallon jugs for constant drainage and suction bottles.
3. Mineral oil bottles for urine specimens.
4. Prescription and dropper bottles for pharmacy use.
5. Litmus paper bottles for tablets.

6. Mayonnaise jars for sterile packing, applicators, tongue blades in the supply room.

Rubber economies that are proving satisfactory include:

1. Sewing patches on rubber draw sheets where soft spots appear.
2. Converting old intravenous tubing to tourniquets and also using it for irrigation purposes.
3. Demoting larger bore constant drainage tubing to irrigating cans.
4. Substituting household for surgical gloves for cleaning and for the bedside care of isolated patients with open lesions.
5. Using synthetic rubber rectal tubes. The length of service of these tubes offsets the additional expense many times over.

As a timesaver we have issued to the nursing units the smallest and brightest colored bonbon cups available to substitute for medicine glasses in serving tablet medications. Much less time is spent in washing medicine glasses and the breakage has been greatly reduced.

To conserve ointment tubes, we have discontinued the use

pathology at Jefferson Medical College, spoke on "The Prevention and Practical Management of Shock."

A discussion of gasoline rationing for Queens County was given by Mr. James Lundy, OPA chairman for Queens.

. . .

The Friday afternoon talk on February 19 will be "Treatment of Varicose Veins," by Dr. Gerald H. Pratt, associate surgeon and chief of vascular surgery, New York Post-Graduate Hospital Out-patient Department.

Richmond County

Dr. H. Lynn Halbert, of Grymes Hill, conducted his first meeting as president of the Richmond County Medical Society on February 10 in the Richmond Health Center, St. George.

At the Helm

Arthur B. Stiles, of Owego, was elected president of the Tioga County General Hospital at the annual meeting of the board of directors and staff at the Jenkins Inn in January.

Mr. Stiles, postmaster at Owego, has been active in support of the hospital since the campaign to erect an institution to serve all of Tioga County, and he is a past president as well as a member of the board of trustees and of the executive committee.

Other officers for the coming year will be: Nathan Turk, first vice-president; Leonard R. Chubb, second vice-president; Jesse Hart, third vice-president; Luther Hardy, secretary; and Earl C. Cooper, treasurer.

The executive committee, to be headed by Mr. Stiles, will consist of: B. J. Cotton, Arthur S. Buckley, Luther C. Hardy, Edward W. Eaton, Earl C. Cooper, Hart I. Seely, Elwin H. Johnston, William C. Farley, Floyd J. Beers, Clifford B. Dounce, and Harry S. Fish.*

. . .

Cornwall Hospital board of directors at their annual meeting in the hospital on January 21 re-elected Col. Harry M. Scarborough as president. Vermont Hatch remains as vice-president; Harry E. Keever, treasurer; and William B. Cocks, secretary.*

. . .

Mason B. Coger was elected to his twelfth successive term as president of the Corning Hospital board of directors in December. Also re-elected were John LeValley, vice-president, and W. W. Oakley, secretary-treasurer.*

. . .

Frederick P. King, of Sunnyside Lane, was re-elected president of the Tarrytown Hospital Association at the annual meeting held at the hospital on January 18. At the same time John Hunter, of Barney Park, was re-elected treasurer, and Ellery Wright and Wallace Odell, both of Tarrytown, were designated vice-president and secretary, respectively.

The board of directors of the hospital remains the same with the exception of Donald K. Luke, of Fargo Lane. The members re-elected, besides Mr. King, Mr. Wright, Mr. Hunter, and Mr. Odell, were Harold V. Engh, of Irvington, and John D. Rockefeller, III, of Pocantico Hills.

New equipment, it was stated in a report to the board, has been installed in the x-ray department, the laboratory, the emergency room, and the maternity ward, with special mention going to the Duchess de Talleyrand's generous gift of an iron lung.*

. . .

At the annual meeting of the Benedict Memorial Hospital, Ballston, held in January, the following officers of the institution were re-elected: president, Wright Scidmore, Jr.; first vice-president, William Rooney; second vice-president, Mrs. W. A. Andrews; secretary, Mrs. H. B. Dorman; treasurer, Samuel S. Newton; directors for four years, Mrs. John Knickerbacker, Edward J. Morley, and Samuel S. Newton.

During the year Ralph B. Dunton and Harold Arff were elected directors to fill vacancies caused by the deaths of Stephen B. Merchant and George Ashton.*

. . .

Dr. Alfred K. Bates was elected president of the staff of Auburn City Hospital at the annual meeting of the staff in January. Other officers elected were: vice-president, Dr. G. Perry Ross; secretary, Dr. J. Burnett Atwater.

Those present at the program that followed the meeting, including wives of the staff members, were welcomed by Jerome F. Peck, Jr., acting superintendent of the hospital. Dr. Walter B. Wilson, retiring president, introduced the Student Nurses' Glee Club, which amply demonstrated the ability of the members as musicians. The group was given an enthusiastic reception.

Dr. H. I. Davenport presented a plaque bearing the names of members of the medical staff now in the country's service.*

Newsy Notes

New York City's Welfare Hospital for Chronic Diseases will now be known as the Goldwater Memorial Hospital.

. . .

A 9-year-old boy who had his 110th blood transfusion at Mount Sinai Hospital in New York City on January 4, became the 500,000th case of the institution since it was founded by New York's Jewish community in 1852. The boy, victim of a rare malady known as aregenerative anemia, was brought to the hospital first in 1935.

Since then he has visited the institution usually once a month, accompanied by his mother. His name was withheld, but it was learned that he was president of his class in a Brooklyn public school, stood first in scholarship, and was active in sports. He was taking the transfusions as a "routine," his mother explained.

Hospital officials said the records showed that Case No. 1 was a 41-year-old immigrant—operated on for a fistula.

The hospital's first home was a four-story building in West Twenty-eighth Street, where 225 patients were admitted in the first year. Last year it treated 17,000 patients, in addition to 27,000 in clinics. The hospital now occupies eighteen buildings on the three blocks in Fifth Avenue between Ninety-eighth and 101st Streets.*

. . .

Gratitude for the service the Richmond Memorial Hospital, Dreyfus Foundation, emergency medical unit has rendered is expressed by Dr. Edward M. Bernecker, Department of Hospitals commissioner in a letter to John H. Olsen, superintendent of the Staten Island institution.

of shaving cream for surgical preparations, using soap solution instead. Cold cream is issued only in jars to the nursing units.

The operating room discovered that the metal ends of adhesive packages serve admirably for needle holders in the sterilizers if holes are punched in them.

The heating elements of old inhalators make satisfactory hot plates.

Chemical heating pads to which a tablespoon of water is added may have to replace hot-water bottles.

Improvements

In Beth Moses Hospital, Brooklyn, the patient receiving treatment for varicose veins stands up and takes it in comparative comfort, thanks to the inventive mind of Fanny Schlein, director of the outpatient department. Mrs. Schlein noted every now and then that some patient who was being treated while standing on an examining table would suffer from dizziness and general insecurity. So she conceived the idea of a platform that she describes briefly as follows: "A discarded metal bed-raiser and some lumber, found in the carpenter's shop, with four casters which are fastened to the tubular legs of the stand are all there is to it. The result is that the physician and the patient both have greater comfort since the doctor is seated while administering treatment and the patient feels secure in gripping the frame.

"The platform also has the advantage of being small in size and easily stored in a limited space. Taking into consideration our national watchword of 'priority,' we have found this device extremely helpful."—*The Modern Hospital*

A hospital service to handle emergencies which might arise in the Schenectady-Albany area is being set up under the emergency medical service of the civilian protection plan.

The plan will be the first of its kind in the country and will be known as Albany Affiliate Base Hospital 1. The unit will be commanded by Dr. J. Lewi Donhauser, of Albany, who will be commissioned a lieutenant colonel in the public health service reserves. Several Schenectady physicians are expected to be among the personnel, which will include four physicians, five surgeons, x-ray and laboratory technicians, a pathologist, and a dentist, in addition to nurses.

The hospital is also to evacuate patients from Ellis hospital and two Albany hospitals in case of necessity. Members of the unit will serve on army pay when called for emergency duties.*

Cancer clinics in Westchester County that are on the approved list of the American College of Surgeons are conducted by the following hospitals: Mount Vernon, New Rochelle, United (Port Chester), Grasslands (Valhalla), St. Agnes (White Plains), White Plains, and St. John's Riverside (Yonkers).*

The granting to authorities of Brooks Memorial Hospital in Dunkirk of a priority for building materials will make possible advertisement for bids for the construction of the proposed easterly wing of the new structure which is now in use.

We have also found that razor blades can be satisfactorily sharpened by rubbing both sides of them against the inside of a smooth glass tumbler. We have reduced our consumption from 500 to 200 every two weeks.

The propaganda to conserve specified supplies for the war effort has aroused an interest toward protecting all our resources. The storeroom orders from all divisions have markedly and spontaneously decreased, including the amount of breakage. Apologies and explanations frequently accompany requisitions.

The Federal Works Administration originally approved the grant on January 9, 1942, and President Roosevelt gave his approval on March 28, 1942. However, the project could not be started because priorities for critical materials could not be obtained at that time.*

Construction work on Massena's new hospital started in January. The single-story hospital building is a Federal Works Agency project.

The building will be a wooden structure with room for 50 beds. Space is being allowed for additions at a later date when the needs of the community require it. Such additions would make the hospital into one of 100-bed capacity.*

Rochester's oldest hospital, 86-year-old St. Mary's, is now also its newest, as the \$1,300,000 structure replacing the historic institution at Bull's Head stands virtually completed—less than a year from the date its corner stone was laid.

The building will be put into actual operation shortly, it is announced by Dr. Leo F. Simpson, president of the staff and chief surgeon.

A far cry from the small emergency hospital built by the Sisters of Charity in 1857 as the forerunner of the ultra-modern temple of medicine, the new hospital has up-to-the-minute surgical and other equipment, operating rooms, auditorium, staff lounge, dietetic kitchens, private dining rooms, medical and general library, and other modern facilities. It will accommodate 400 patients.

Eventually the old hospital, whose solid gray-stone facade is in striking contrast to the new brick one, will be abandoned. For a while, the ground floor will be used as quarters for sisters and interns.

Long dreamed of, the new building represented a triumph over many obstacles. Plans were prepared about ten years ago, but because of the business depression, no action was taken. After it finally was decided to proceed with the construction, the nation drew closer to war, and Washington already was setting up rigid controls on any project not deemed essential.

Actual construction began June 28, 1941. The project took on civic proportions far beyond mere denominational lines in a campaign to raise \$275,000 for the building fund. It was conducted from January 23 to February 2, 1942. Protestant, Catholic, and Jewish leaders united in soliciting funds, and the drive went over the top by nearly \$40,000.

Sister Martina is superintendent of St. Mary's Hospital.*

In the letter, Dr. Bernecker said: "As we stand at the threshold of a new year, I cannot let the old one go on without letting you know how deeply grateful I am to you and the members of the hospital emergency medical unit for the whole-hearted support and earnest cooperation which has always been so freely and willingly extended to me and to the members of my staff during the past year.

"It would be most difficult to conceive how precarious our situation might have been were it not for the able assistance which we had consistently received from you, whenever the occasion for it arose.

"The great task which still lies before us is by no means finished, but the knowledge that you are there to share the burden with us fortifies us to carry on with renewed enthusiasm and courage."*

Memorial Hospital in Ithaca has announced that "owing to the epidemic of pneumonia and pneumonitis that exists in the community," visiting at the hospital will be restricted "until the emergency is over."

"Visitors coming into the hospital with coughs and colds are a menace to patients, and patients who have chest infections are a danger to visitors," the announcement said.

"The medical staff of the hospital feels it is most essential that only the immediate members of families be permitted to visit the patients during their stay in the hospital, thus offering equal protection to both patients and visitors."*

For the benefit of the United Hospitals Fund, the Juilliard School of Music presented a concert on February 5 in Carnegie Hall. Artists participating in the program, besides the orchestra of the Juilliard Graduate School, included Josephine Antoine, soprano; Muriel Kerr, pianist; Carroll Glenn, violinist; Felix Salmond, cellist; and Albert Stossel, conductor. The entire proceeds went to the United Hospitals Fund.

The end of 1942 marked the close of its fiftieth year for the Little Falls Hospital. This institution is unique in that its board of directors has always been composed entirely of women.

At the close of its seven months' existence, the Blood Derivatives Laboratory at Grasslands Hospital had collected a total of 1,243 units of blood from 1,449 donors.

Soon after its establishment, through a grant from the Martha M. Hall Foundation, the project was officially sponsored by the Westchester County Medical Society and the County War Council, and a goal of 1,000 units was decided upon.

A course for training nurses' aids in Monroe County is being given at the Monroe County Hospital.

Two of Buffalo's oldest hospitals are departing from the specialized trend they have followed for more than eighty years, while a third, known throughout the medical world for its research leadership, is changing ownership.

Providence Retreat, 82-year-old institution for the treatment of mental and nervous disorders, will be used exclusively for maternity cases in the future.

St. Mary's Infant Asylum and Maternity Hospital, will be converted into a hospital for infants and children only.

Central Park Hospital is being taken over by the Sisters of St. Francis but will be operated along the same lines of general hospitalization it has followed since it was opened in 1929.*

Fellowships for research at Mount Sinai Hospital, New York City, have been awarded two Latin American physicians, Dr. Enrique Washington Lithgow, of the Dominican Republic, and Dr. Oscar Martinez Gomez, of Mexico. The fellowships, covering a year of research at the New York hospital, are supported by the Dazian Foundation for Medical Research for the purpose of strengthening good will between the United States and Latin American countries.

At the Christmas party of the Rockville Centre League for Mercy Hospital, the league's Christmas check was presented to the hospital.

Executives and outstanding personalities in journalism and literature participated in the celebration of the twenty-first anniversary of Beekman Hospital in New York City, which was held at the Bankers Club on January 16.

The meeting also marked the beginning of a campaign for \$125,000 to meet the deficit in operating this institution for the benefit of 1,000,000 workers and thousands of residents in the financial district of lower Manhattan.

Howard S. Cullman, president of the hospital, spoke of the progress of the institution since its establishment in meeting the increasing needs of that section of the city.

"The health protection, the necessary facilities for efficient and prompt treatment of the injured and ill in this crowded port and financial district are of primary importance to the nation and to the war effort," he said.

Mr. Cullman also read a telegram from former Governor Alfred E. Smith, a member of the board of directors, who was ill. Mr. Smith wrote that with the exception of the years spent in Albany this was the first time he had failed to attend the annual meeting.

Paul Schubert, radio commentator, Eric T. Winberg, correspondent in Sweden, and William L. White, author, spoke in support of the hospital's program.*

AWARD FOR RHINO-LARYNGOLOGICAL RESEARCH

Money is now available from the Casselberry Fund of the American Laryngological Association for a prize award for original research in laryngology or

rhinology. Competing theses must be in the hands of Dr. Arthur W. Proetz, secretary, 1010 Beaumont Medical Building, St. Louis, before March 1, 1943.

Medical Legislation

The following bulletin (No. 2) was issued on January 26 by the Legislative Bureau of the Medical Society of the State of New York.

State Legislation

Bills are not coming in as rapidly this year as in some previous years but we are getting our share and, without doubt, before the close of the session we shall have at least the usual amount of legislation to consider. We hope that the committees will report promptly upon the bills as they are being sent out so as to avoid a clog or bottleneck later on. There is some indication that the two houses may dispose of legislation a little more rapidly this year. We shall appreciate, therefore, a prompt report of your comments upon the bills.

Among the bills that have been introduced which we shall report in an informational way are the following:

Both houses have been asked to extend to July 1, 1944, the Health Commissioner's authority to embargo milk supplies that he believes to be dangerous, or to transfer milk from one plant to another to prevent sabotage or enemy action.

Several bills have been introduced proposing extension of the coverage of the Workmen's Compensation Law. They would include farm laborers, domestic workers, workers in restaurants, bars, grills, lunch rooms, and luncheonettes, as well as employees of municipal corporations, nonprofit associations and corporations—educational, religious, charitable institutions; chauffeurs in New York City, and employers with fewer than four employees.

New Bills Introduced

Senate Int. 206—W. J. Mahoney; Assembly Int. 279—Kreinheder, provides that license to practice physiotherapy shall not permit holder to administer drugs and [instead of or] practice medicine except that the treatment of *quarantinable diseases* [instead of *diseases*] must be under supervision of physician. Referred to the Education Committees.

Comment: Those licensed to practice physiotherapy under the law have not been trained as physicians. They have had no training in the diagnosis of diseases, hence would not be in a position to know when they should call a physician to assist them because of the presence of a quarantinable disease. Unless by training they would be able to diagnose the presence of a communicable disease, it really would be necessary for them to have the assistance of a physician's opinion in every case they take, and that is exactly what the law provides at present. If the supervision of the physician is removed, it is also conceivable that they could do a great deal of harm by treating cases of unsuspected cancer or diabetes or heart disease, or a number of other conditions that only a physician can discover in the early stages, which is a most important period in the progress of a disease. This bill is definitely not in the interest of the public welfare and should not be enacted.

Senate Int. 278—W. J. Mahoney; Assembly Int. 335—Mailler, authorizes Governor, on recommendation of State Health Commissioner, to designate emergency health and sanitary areas when inadequacies of medical facilities or personnel caused by national emergency exist in any area in State;

State Health Commissioner to cooperate with local health and welfare agencies and employ necessary medical and health personnel. Referred to National Defense Committee in the Senate and Health Committee in the Assembly.

Comment: Certain rural areas of the State are suffering for lack of adequate medical care because of the physicians' going into service. There are very few such areas at present, but as the armed services increase in number more and more physicians will be required and there may come a time when it will be necessary to help certain communities secure physicians, as is now the case in some other states. The rapid growth of population in the vicinity of permanent camps and war industries presents a similar problem. Under the Procurement and Assignment Committee, which is now a part of the War Manpower Commission, physicians may be allocated to such areas under the Federal Government. This bill is an attempt on the part of New York State to assist the government by making provisions of its own. The precautions required seem an adequate safeguard to the development of state medicine. In the first place, the Governor must declare that an emergency exists in that area and, with the assistance of the Commissioner of Health, he can then locate physicians as they may be needed. The arrangement is just for one year; the law will automatically expire at the end of that time and if a longer period is required it must be reintroduced.

Senate Int. 301—Young, provides that a town board in any town having a town physician and containing two hamlets separated by more than twenty miles by nearest traveled route, may establish office of assistant town physician. Referred to the Internal Affairs Committee.

Comment: Under the town law a town has authority now to establish the office of town physician and employ a practicing physician on salary if there is not a practicing physician in that town. This amendment would give the town authority to employ, in addition, an assistant physician where two or more adjacent towns are without a physician.

Senate Int. 311—Hampton; Assembly Int. 362—Emma, provides that no manufacturer, bottler, packer, or wholesaler of drugs shall sell poisonous, deleterious, or habit-forming drugs or medicines to any person, firm, or corporation not registered by State Pharmacy Board, except to the State, any political subdivision, hospital or dispensary or physician, dentist, or veterinarian. Referred to the Education Committees.

Comment: This bill has been considered in previous years. It is sponsored by the New York State Pharmaceutical Association and aims to prevent the sale of habit-forming drugs by stores other than licensed drug stores, by prohibiting the manufacturer or wholesaler from selling the drugs to such stores.

Senate Int. 328—Bewley; Assembly Int. 377—Whitney, provides for reasonable personal income

AN OLD TIMER CARRIES ON!

The esteemed, venerable practitioner is still carrying on! In many instances, our old friends are coming out of retirement to fill the gaps resulting from enlistment of their younger colleagues in the armed forces.

Another old friend and veteran in the armamentarium of the practitioner, Arsenoferratoze, is also carrying on! Modern therapeutics recognizes the value of Arsenoferratoze in the treatment of the anemias found in pregnancy, parturition, lactation, x-irradiation, and chronic hemorrhagic and iron deficiency diseases.

In addition, today's needs have logically extended the indications for Arsenoferratoze... To counterbalance

the blood changes in sulfa-drug therapy... To act as a replacement factor for blood donors... To safeguard against iron deficiency in the restricted diets of defense workers.

The old practitioner specifies Arsenoferratoze because it has "proved its metal" in many years of service. He knows that it is pleasant to take, easily and readily assimilated, and decidedly non-irritating. Arsenoferratoze serves a dual purpose—acting as an efficient hematinic and as a suitable alterative. Its palatability makes it especially suitable for children.

ARSENOFERRATOZE
HEMATINIC AND ALTERATIVE OF CHOICE

Dosage: One to three teaspoonfuls, 2 or 3 times daily, with meals. *Supplied:* plain, or with copper, in bottles of 8 fluid ounces; in tablets, bottles of 75.

tax deductions for unusual medical expenses, including cost of childbirth, for life insurance premiums, and for exempting dependents over eighteen years of age in full-time attendance in an accredited college or school. Referred to the Taxation Committees.

Assembly Int. 135—Austin, provides for removal and destruction of ragweed and other weeds and plants detrimental to public health on determination of municipal board; notice and opportunity are given owner before local board enters property. Referred to the Health Committee.

Assembly Int. 333—C. D. Williams, authorizes

State Education Board until January 1, 1944, to license without examination as professional nurse any person who in the preceding ten years lived in and practiced nursing in the State and was unable to meet all preliminary or professional requirements. Referred to the Education Committee.

Assembly Int. 334—C. D. Williams, provides that during and until one year after discharge from active service in the U. S. armed forces as member of medical, hospital, or similar unit, applicant may be licensed by Education Department as registered professional nurse upon furnishing satisfactory evidence. Referred to the Education Committee.

Federal Legislation

Several bills of definite importance to us are pending before Congress:

S. 345, by Mr. Murdock, of Utah, and *H.R. 786*, by Mr. Tolan, of California, would include chiropractors, together with physicians and osteopaths, as qualified to treat cases under the United States Employees' Compensation Act. Congressman Tolan had this bill before the last Congress but could not get it out of Judiciary Committee. The bill is with the Judiciary Committee again and we suggest that you write to your congressman opposing its enactment.

S. 400, by Mr. Thomas, of Utah, and *H.R. 649*, by Mr. Bulwinkle, of North Carolina, provide for the reorganization and functions of the Public Health Service, in that hereafter the Public Health Service in the Federal Security Agency shall consist of the office of the Surgeon General, the National Institute of Health, the Bureau of Medical Services, and the Bureau of State Services. All of the functions of the Public Health Service are

to be divided among these four divisions. The chiefs of the National Institute and of the two Bureaus shall be commissioned medical officers detailed by the Surgeon General from the regular corps.

Another Bill, *S. 450*, by Mr. Pepper of Florida, provides benefits for the injury, disability, death, or enemy detention of civilians and for the prevention and relief of civilian distress arising out of the present war. Medical benefits, including doctor's and nurse's services, drugs and other medicines, prosthetic and other appliances, hospitalization, and other reasonable services for treatment and care, shall be provided.

REVIEWED

Demonstrations of Physical Signs in Clinical Surgery. By Hamilton Bailey, F.R.C.S. Eighth edition. Octavo of 336 pages, illustrated. Baltimore, Williams & Wilkins Co., 1942. Cloth, \$7.00.

This is an excellent treatise on the art of clinical surgical diagnosis. The book is well written, profusely illustrated with good photographs, and furnishes an excellent review of most of the problems one is apt to encounter.

The material is generally arranged according to the various anatomic sections of the body and is tersely presented. Careful reading will give the surgeon, the general practitioner, or the medical student a good review of the entire subject and may bring back to memory many important facts once learned but long since forgotten.

In this era of complicated laboratory procedures, involving even simple diagnostic problems, it is very refreshing to review once again what one can do by judicious employment of eyes, hands, ears, and gray-matter.

This book deserves a place in the library of anyone interested in clinical surgical problems.

WILLIAM I. SHEINFELD

Diseases of Metabolism. Detailed Methods of Diagnosis and Treatment. A Text for the Practitioner. Edited by Garfield G. Duncan, M.D. Quarto of 985 pages, illustrated. Philadelphia, W. B. Saunders Company, 1942. Cloth, \$12.

It is the opinion of the reviewer that this is the best book on the subject of diseases of metabolism in the English language. Dr. Duncan himself is responsible for the presentation of the material on diabetes, which comprises one-third of the entire volume. The other contributors are men who are all experts in their fields.

The metabolism of various food components, minerals, water, and vitamins is discussed, both in

health and in disease. Then come detailed discussions of the following diseases in nutrition: obesity, xanthomatoses, gout, hyperinsulinism, and diabetes. The subjects are all complete and up to date, and much of the material is devoted to practical therapeutics. The entire book is clear and well written. There is an appendix listing foods and their composition, and there are also tables of normal weights. One of the best chapters is that by Peters dealing with water balance in health and disease. He has in this chapter simplified what is ordinarily an extremely difficult subject for the practicing physician to understand. Dr. Peters has also brilliantly discussed the practical significance of disturbances in water balance in many of the diseases with which the internist is confronted.

This volume is a good reference book and belongs on the desk of every practicing physician.

WILLIAM S. COLLENS

The Principles of Neurological Surgery. By Loyal Davis, M.D. Second edition. Octavo of 503 pages, illustrated. Philadelphia, Lea & Febiger, 1942. Cloth, \$7.00.

This is an enlarged and revised edition of the 1936 publication of *The Principles of Neurological Surgery*. The author's added experience with a wide variety of lesions of the nervous system is reflected in the present edition. The treatment of tumors, injuries, and infections of the brain and spinal cord and their coverings is well discussed. Illustrative case histories are effectively used throughout. In addition there are chapters devoted to the diagnosis and treatment of pain, the congenital anomalies of the nervous system, the lesion that may be altered by surgery on the sympathetic system, and a variety of disorders less frequently encountered by a neurologic surgeon. As stated by the author, the subject is presented in an abbreviated form in order that the present-day knowl-

(Continued on page 374)

Presenting the "KOROMEX SET COMPLETE"

*Koromex Set Complete** provides the long expressed need for a compact unit containing the three important items used for approved contraceptive technique. This attractive and strongly built case is identified by an easily removed label, convenient for dispensing or prescription purposes. To order or prescribe, merely write, "*Koromex Set Complete. Diaphragm Size_____*"

KOROMEX DIAPHRAGM—The outstanding, most durable diaphragm made. Backed by the most extensive record in clinical use ever attained by any diaphragm. In special sanitary pouch.

KOROMEX TRIP RELEASE INTRODUCER—The latest development in introducers. Swivel tip facilitates usage.

KOROMEX JELLY and H-R EMULSION CREAM—Both preparations have equally high spermicidal value, but differ greatly in the amount of lubrication afforded. A tube of each is here offered so the patient may determine for herself which type of preparation better meets her aesthetic requirements and her personal preferences

*Price of the Koromex Set Complete is only that of the Koromex Diaphragm and the Koromex Trip Release Introducer.

JEFFERSON BROWDER

Recent Advances in Obstetrics and Gynaecology. By Aleck W. Bourne, M.A., and Leslie H. Williams, M.D. Fifth edition. Octavo of 363 pages, illustrated. Philadelphia, The Blakiston Company, 1942. Cloth, \$5.50.

When one endeavors to record in textbook form the recent advances of any department of medicine, he has chosen a big job. If such a writer is successful, however, a very helpful instrument for those interested is the result. The authors of the fifth edition of *Recent Advances in Obstetrics and Gynaecology*, have, as usual, turned out a very helpful volume. They present briefly and clearly a résumé of all recent material that is of permanent value in obstetrics and gynecology. It goes almost without saying that all this material is not new. On the other hand, the old is "polished up" and thereby brought up to date so that the reader may, with a minimum of time, review the subject and emerge well informed. Time is paramount in these days of "stress and strain" and "blessed be he" who can save precious time and give up-to-date information at the same sitting.

If one must offer specific examples of "best material" in this volume, your reviewer would mention in the division on obstetrics Chapter II ("Post-natal Care"), and Chapter VII ("Radiology in Obstetrics"); in gynecology Chapter XII ("The Sex Hormones") and Chapter XIII ("Ovarian Tumors").

This small volume contains much valuable information. It is written in a terse, flowing, interesting style. One might be ultramodern and truthfully say "it has much packed in little space."

HARVEY B. MATTHEWS

Clinics. Volume 1, No. 1, June, 1942. Edited by George M. Piersol, M.D. Octavo of 264 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1942. Paper, Bi-monthly, \$12 per year.

With this issue, the *International Clinics* alters its policy and name. Henceforth this fine publication will be named *Clinics* and will appear every two months instead of every four.

The present number concerns itself with burns (Ravdin, Harkins) and shock (Rhoads, Scull, Meakins).

There are good clinics from New Orleans, and a good review from Cincinnati on peripheral blood vessels.

ANDREW M. BABEY

Cabot and Adams Physical Diagnosis. Thirteenth edition by F. Dennette Adams, M.D. Octavo of 888 pages, illustrated. Baltimore, Williams & Wilkins Company, 1942. Cloth, \$5.00.

The general form of this edition follows the previous one, being an enlargement of the standard, valuable work of Richard C. Cabot, a favorite text of many students and practitioners since the first edition of 1900.

The plan of the first author in presenting only the subjects with which he had personal experience has given way to one in which the present author has drawn also upon the experience of his colleagues, mainly from the Massachusetts General Hospital.

A general revision has been made of many sections, especially those on the mouth and teeth, pulse,

heart murmurs, and coronary heart disease. There are 400 excellent illustrations to clarify the text of nearly 900 pages.

W. E. McCOLLOM

Heredity, Food, and Environment in the Nutrition of Infants and Children. By George D. Scott, M.D. Octavo of 778 pages. Boston, Chapman and Grimes, 1942. Cloth, \$5.00.

This is by far the most satisfying book on child nutrition that this reviewer has seen in many years.

It is written with a plan and a purpose. It is original throughout in every way and is not to be regarded as having been copied from various references. Especially commendable are the detailed discussion on the individual food articles, pertinent facts in infant nutrition, and various phases of metabolism.

The book contains a store of information that will prove of value in handling feeding problems in infants and children.

Furthermore, it may be recommended to medical men as well as to students of nutrition. We believe, however, that it is a bit too academic for the average parent or social worker.

HARRY APPEL

Memorable Days in Medicine. A Calendar of Biology and Medicine. By Paul F. Clark and Alice S. Clark. Octavo of 305 pages, illustrated. Madison, University of Wisconsin Press, 1942. Cloth, \$2.00.

In this unusual little book the Clarks have tabulated, under each of the days of the year, the birthdays and deathdays of many of the great figures of medicine and biology. The anniversaries of many great achievements in the field of medicine are listed as well. There are brief biographies and descriptions and numerous small but well-chosen illustrations.

This volume is obviously a labor of love, and the Clarks have succeeded in accomplishing their purpose admirably. Many persons will be interested and entertained in looking up the events which occurred on their own birthdays. The total achievement is minor but worth while.

MILTON PLOTZ

Physicians' Reference Book of Emergency Medical Service. A Compilation, Chiefly from Medical Literature, Presenting the Practical Experience and Lessons Acquired in Handling Civilian War Casualties. Octavo of 268 pages. New York, E. R. Squibb & Sons, 1942. Paper.

E. R. Squibb & Sons must be warmly congratulated on the excellent book they have published for the medical profession. This reference book is a compilation, chiefly from British and American literature, of a vast amount of useful information on the management of civilian war casualties. There are three sections; one on precautionary measures; another on hospital service; and a final extraordinary chapter on the management of war injuries. The latter includes excellent reviews on shock, burns, fractures, crush, and blast injuries. This book is highly recommended to all physicians.

ANDREW M. BABEY

Industrial Surgery, Principles, Problems and Practice. By Willis W. Lasher, M.D. Enlarged First Edition. Octavo of 472 pages, illustrated. New York, Paul B. Hoeber, Inc., 1942. Cloth, \$6.50.

New Colloidal Cream Soap ... a neutral, effective cleanser

CREAM OF SOAP is neutral (pH 7.5), yet is one of the most effective skin cleansing agents. Because of its colloidal form it adsorbs grease, skin wastes, and dirt. It is rubbed on the dry skin, then rinsed off with water. No case of irritation has been observed or reported when used as a cleansing adjunct in dermatological cases. Unaffected by acid skin or hard water. Leaves the skin soft, smooth, and supple. CREAM OF SOAP is accepted for advertising by publications of the A.M.A. and is advertised to physicians only. Retail \$1. a jar. Samples to physicians on request.

CREAM OF SOAP, 55 W. 16th St., New York, N. Y.

GALATEST GOES TO WORK IN WAR FACTORIES!

The Medical Departments of leading War Industries have been sending in urgent orders for GALATEST — the dry reagent for instantaneous detection of urine sugar.

Tests made at these plants must be done with maximum speed — accuracy — convenience. GALATEST has ALL these qualifications.

ACCEPTED FOR ADVERTISING IN THE JOURNAL OF
THE AMERICAN MEDICAL ASSOCIATION

SPEED—Urine sugar test in 30 seconds.

ACCURACY—No false reactions.

CONVENIENCE—A single drop of urine. No test tubes. No boiling.

LIPOLYSIN

MALE

FEMALE

[Continued from page 375]

This is a comprehensive work, having been brought completely up to date. Every conceivable type of injury, particularly as it relates to industry and compensation, is discussed in detail.

When necessary to understand the problem better, sufficient pathology is introduced to make the discussion easily understood. In addition to discussion of the more common trauma to the extremities, there are excellent chapters dealing with cranial injuries, abdominal injuries, and hernia.

In the last chapter chemotherapy and dehydration are discussed. This book is highly recommended for the general practitioner as well as for the surgeon. It is timely that it appears now when the physician may be called upon to care for surgical conditions resulting from accidents which will occur incidental to the ever-increasing employment in the industries associated with the war production program.

MERRILL N. FOOTE

American Surgeon Abroad. By Richard A. Leonardo, M.D. Octavo of 235 pages, illustrated. New York, Froben Press, 1942. Cloth, \$2.50.

The premise of this book is the advantages of a European postgraduate course in preparation for a career in surgery. The author made trips to various clinics in Europe in 1924, 1925, 1936, and 1938, spending most of his time in Vienna and Budapest. "In Hungary in one year's time I obtained more postgraduate surgery than would have been possible in two or more years in a surgical residency in my home city" (The doctor comes from Rochester, New York.)

The book is, however, really a medical travelogue, with enough historical and political references to add to its local interest. There are repeated descriptions of the fine courses in surgical pathology and operative surgery on cadavers. It is evident that the day of independent surgery on living patients by nonresident surgeons from outside the homeland is over, as witness the laws passed by Hungary in 1936. The illustrations are essentially photographs—yes, signed photographs, of the distinguished teachers under whom Dr. Leonardo was privileged to study.

For comparative study in the approach to training in surgery a book published in late 1942, *The Making of a Surgeon*, by Dr. Ernest V. Smith, will deserve a reading. Dr. Smith stresses the surgical residency in some large American center—in his case the Mayo Clinic.

JOSEPH RAPHAEL

Sulfanilamide and Related Compounds in General Practice. By Wesley W. Spink, M.D. Octavo of 374 pages. Chicago, The Year Book Publishers, 1942. Cloth, \$3.00.

The same high standard of the first edition is maintained in this latest edition of the volume on chemotherapy by Dr. Wesley Spink of Minnesota. It is brought up to date with facts on the less well-known "intestinal disinfectants," and is sprinkled with good case studies that illustrate salient facts of treatment. It is an excellent book.

ANDREW M. BABY

Contraception and Fertility in the Southern Appalachians. By Gilbert W. Beebe, Ph.D. Octavo of 274 pages. Baltimore, Williams & Wilkins Company, 1942. Cloth, \$2.50.

Although this book concerns itself chiefly with the population of the southern Appalachians, other areas are incorporated in the study in order to en-

able one to draw more general conclusions and hence to augment its intrinsic value.

The book is written in an interesting fashion, and the author avoids the usage of many complicated biologic terms. Dr. Beebe is successful, also, in conveying a consistent pattern of thought in which he shows that variation in fertility is mainly a result of birth control.

The volume is timely, well written, and concrete.
S. L. SIEGLER

Surgical Pathology. By William Boyd, M.D. Fifth edition. Octavo of 843 pages, illustrated, Philadelphia, W. B. Saunders Company, 1942. Cloth, \$10.

This fifth edition of Boyd's *Surgical Pathology* has been thoroughly revised in text and illustrations. To quote from its preface, "new subject matter includes head injuries, wound infections, anaerobic streptococcal infections of the skin, burns, dermatofibroma, Hurthle cell tumor, duodenitis, chronic ulcerative colitis, liver death, bile peritonitis, pyelonephritis in relation to arterial hypertension, acid phosphatase in carcinoma of the prostate, interstitial endometrioma, plasma cell mastitis, fibrosing adenomatosis of the breast, osteomyelitis of the frontal bone, Arnold-Chiari malformation, skeletal lipid granulomatosis, injuries and tumors of the nerves, synovial sarcoma, Ollier's disease, Morguio's disease, osteoid-osteoma, reticulum sarcoma, liposarcoma and eosinophilic granuloma of bone."

There has been included the surgical pathology of the middle ear and the thorax. The reviewer feels that this may be convenient for the surgeon and perhaps flattering to the specialist, but after all the thoracic organs are parts of systems and should be treated as such rather than in a sketchy few pages.

To those who are familiar with the previous editions of this work, there is no need to extol the excellence of it. However, to those who are not, the reviewer sincerely suggests that they immediately acquaint themselves with it. For the surgeon and the pathologist it contains a wealth of necessary information, and for the general practitioner and the student it presents an admirable picture of surgical pathology of today.

MAX LEDERER

Superior Children Through Modern Nutrition. How to Perfect the Growth and Development of Your Children from Birth to Maturity. By I. Newton Kugelmass, M.D. Octavo of 332 pages. New York, E. P. Dutton & Company, 1942. Cloth, \$3.50.

During the past decade there has been a growing tendency to feed and handle children from a group standpoint. This has come about through the establishment of more and more well-baby clinics. Since in many instances these clinics have become overcrowded, babies usually have to fit the formulas and routine used in these clinics. In other words, the baby has been lost sight of as an individual and as a composite whole. Therefore, this book, written for parents who have infants and children to rear, stresses individualization as to diet and all other phases of health routine.

The scientific selection of food to make up a normal dietary is well handled in this volume.

After reading the book, it should be easy for one to figure out a well-balanced diet even in these days when rationing is becoming a problem.

THURMAN B. GIVAN

PLAIN, UNFLAVORED KNOX GELATINE

Recommended by Physicians
for special dietaries in treatment of:

... Peptic Ulcer ... Reducing
... Diabetes ... Convalescence
... Colitis ... Infant Feeding
... Debility

caused by lack of adequate protein

NOTE: Knox Gelatine should not be confused with ready-flavored gelatine dessert powders. They are only about 1/2 protein, mostly acid-flavored. Knox is all gelatine, no sugar...a pure wholesome protein. Contains 7 of the 10 essential protein parts.

If you would like information, reprints or suggested recipes for any of the above, simply check the subjects, clip this ad to a prescription blank and mail to Knox Gelatine, Dept. 474, Johnstown, N. Y.

nascent OXYGEN for DRESSINGS

CLINICALLY TESTED* As a surgical dressing: gauze, saturated with STA-O-GEN (a) does not adhere to wounds (b) reduces discharge (c) eliminates unpleasant odor (d) wounds heal faster and appear healthier (e) dressings are easily applied, continue effective longer and cause no burning or pain when changed (f) there is no irritation of the skin about the wound edge (g) the product is stainless.

STA-O-GEN is a bland ozonide of olive oil. On application, it releases nascent oxygen continuously for hours — deodorizing, germicidal, fungicidal, healing. Available in Liquid or Ointment form. Liquid also in capsules (Vag-I-Caps) for leukorrhea. Drug-gists may obtain from any jobber. Latimer Laboratory, Inc., 41 E. 21 Street, N. Y. C.

*Cowett: Meet. N.Y. Proc. Soc.—Apr. 15, 1942

GIVES EXCELLENT RESULTS

Cuts short the period of the illness and relieves the distressing spasmodic cough. Also valuable in other Persistent Coughs and in Bronchitis and Bronchial Asthma. In four-ounce original bottles. A teaspoonful every 3 to 4 hrs.

GOLD PHARMACAL CO.

NEW YORK CITY

TUBERCULOSIS AND THE WAR—CANADA

The fall in the death rate from tuberculosis in Canada, which has been so evident for the past quarter of a century, has occasioned in some quarters a false sense of security. Nothing could be more unsound or misleading. A disease that kills nearly 6,000 of the population, leaves at least 30,000 incapacitated, and costs the country directly at least \$8,000,000, annually, is still a formidable enemy and a major public health problem.

If control of tuberculosis is to be maintained in wartime, tuberculosis services must be continued, problems that arise as a result of the war must be attacked and advantage taken of wartime case-finding projects. Case finding has kept ahead of treatment facilities, which have been inadequate, and until both are developed to a greater degree, control of tuberculosis is still hidden in the future.

Two of the most important phases of case-finding services available are (1) for the general practitioners to provide an early diagnosis, since

this is still the greatest source of cases, and (2) examination of contacts, the next greatest source.

Two opportunities have presented themselves as a result of the war: the x-ray examination of all recruits for the armed forces, and case-finding projects among industrial workers, particularly in war industries. Tuberculosis is two and a half times as great in industry as in the general population. Therefore, the control of tuberculosis is an important phase of industrial hygiene.

Emphasis is being placed on retaining the open case of tuberculosis in sanatoria. Every patient who leaves against advice represents a weakness in the tuberculosis control system. The factors involved should be carefully analyzed and every way possible must be sought to remedy conditions in institutions to offset this failure in efficient segregation.

The Control of Tuberculosis in Wartime, G. J. Wherrett, Can. Public Health Jour., Sept., 1942.

ANOTHER *-.-!!! CONFERENCE

"I hate most conferences," begins a booklet distributed by Hammermill Paper Co. on how to harness a conference, by Don Herold, "but you gotta have 'em."

"I have sat in many a business conference and squirmed in pain at the spectacle of so many high-powered, high-salaried men fiddling their time away so foolishly. A conference can often get nowhere faster than any other form of human cooperative effort. 'Mr. B—— is in conference' has almost become the standard joke for the funny papers when they wish to kid the American business man.

"But conferences are necessary, and they will always have to be held, and some of them move fast and get things accomplished. There is no reason why 12 men in a room should add up dumber than any one of the 12. Twelve men in a room ought to be at least 12 times as smart as any one of them. If managed the right way, 12 men in a room should stimulate, rather than nullify, each other. That is the ideal for a conference.

"But conferences first have to lick their reputation for futility. If the participants in a conference come with an attitude that it is going to be 'just another conference,' it will be just that.

"How can conferences be harnessed? How can their brain-power be diverted from doodling to doing? This booklet does not promise to galvanize all conferences into efficient action. But it will struggle to suggest a few ideas which may help make conferences better."

Some of the ideas recommended by the author suggested more writing and less talking in connection with every conference—the use of printed forms because they help conferences to get down to real business, instead of monkey-business—time should

be given to those called into conference to avoid disruption of everybody's routine work—"conference calling forms" should give advance notice of the subject or subjects to be discussed so the victims will have some chance of thinking ahead—keep conferences brief, the shorter they are the better the result—and check back after a conference to see if the things certain people were supposed to do, were done.

As a closing, the author gives these odds and ends on conferences: "A special file folder on each conference may be a good idea. In this can go carbons of advance notices, memos on the conference, follow-up memos on correspondence, reports on progress, etc.

"Writing pads and pencils should be ready on the table. And of course a suitable supply of ash trays

"Oh, yes, phone calls! Keep them out of the room, if you can. Arrange to have messages taken and call-backs promised, if necessary. Keep your conference on the beam!"

TAKE A SLOGAN

To "get there fustest with the mostest men" has had a great revival in the news of the present world melee. "To little—too late" probably inspired the Greater Boston United War Fund's "Give enough—soon enough!"

Not a bad phrase for a medical practice, for given enough attention—soon enough, almost any case of illness is easily remedied.

"Give until it hurts" might do for a fund raising job, but never in this world for a doctor. Imagine a physician (or a dentist) using this phrase as a driving force!

THE MAPLES INC., ROCKVILLE CENTRE, L. I.

NO TRAVEL RATIONING

In spite of many conjectures that something will be done to curtail civilian rail traffic, the Office of Defense Transportation recently expressed openly an opposition to all plans for rationing travel on our railroads.

The principal weakness of all transportation rationing schemes involves the complexity of railroad travel—the thousands of ticket offices and millions of travelers which would require tremendous administrative rationing machinery.

No democratic country has ever worked out a satisfactory plan. Great Britain has rejected a travel permit system during the war because of its complexity, its demands on manpower for administration, and the inconvenience and delay it would create for those who must travel on necessary business.

During 1941, the railroads carried 254,000,000 persons, exclusive of commuters. With the increase last year to probably 400,000,000, the ceiling has probably been reached. If the railroads were able to manage that job, it will be able to continue doing so—barring fuel problems.

COMPARED TO THOSE, MEDICAL WORDS ARE ABC

A distributor who is a hawk for the unusual sent a folder to his prospective customers with the following fantastic words:

Hottentottenpotentatentatenattentaeter

This word of 38 letters means "Hottentot Potentate's Aunt's Assassin," and the saying of it was used as a test of drunkenness by the Berlin police force in Germany (before Hitler undoubtedly). If you can say it, you are sober.

Chargoggagoggmanchaugoggehaubunagunga-maug

This word of 43 letters is the old Indian name of Webster Lake in Massachusetts. It is possible that Noah Webster took all the letters to be found in his dictionary out of this name.

Llanfairpwllgwyngyllgogerychwyrndrobwllllantysiliogogoch

This word of 58 letters is the name of a town in North Wales and it is said to be the longest name in any language. Translated it means "Church of St. Mary in a hollow of white hazel, near to a rapid whirlpool and to the St. Tysilio's-Church near to a red cave." When the railroad train arrives at this town, the conductor announces, "If there's anybody here for there—this is it."

But, says the distributor, here is the longest word in the English language:

Secretary

THE SALVAGE JOB

Getting every ounce of critically needed waste materials into the flow of manufacturing implements of war is the important task of the Salvage Branch of the Conservation Division, WPB. "Junk" is something that every man, woman, and child must now treat with respect if we are to "get in all the scrap" so vitally needed.

Paul C. Cabot, Deputy Chief of the Conservation Division, declared recently that "if our production schedule is to be maintained 17,000,000 net tons of purchased iron and steel scrap are needed to give the iron and steel furnaces sufficient inventories to prevent shut-downs during the months to come."

To treat this problem, the WPB through its Salvage Branch approaches the problem of "getting in the scrap" in four major ways:

First—An Industrial Salvage Section is charged with the responsibility of educating industry to salvage all critical waste materials, to speed up the return of these materials into the war production stream, and to help industry to use established channels of disposal. Scrap in this effort is classified as "dormant" and "production." "Dormant" scrap is defined as obsolete machinery, tools, equipment, dies, jigs, fixtures, etc., which are unsuitable for current or future use because they are broken, worn-out, dismantled, irreparable, or in need of parts no longer available.

Second—A General Salvage Section is charged with establishing salvage programs in local community areas, appointing local committees and directing their activities. Their salvage operation extends to every household including farms, all retail stores, garages, hotels, small businesses, and the smaller industrial organizations in rural areas. Some 12,500 state and local salvage committees are aiding in this job.

Third—The Special Projects Salvage Section is responsible for salvaging large accumulations of secondary and waste materials that are tied up due to financial, legal, political, and other reasons which impede the work of other Sections in the normal course of operation. Special projects include such things as abandoned railroads, streetcar lines, factories, bridges, etc.

Fourth—The Automobile Graveyard Section, now operating through 254 field representatives, has the job of seeing that some 20,000 graveyards in the country function as producing units. It is essential to keep these automobile graveyards as operating scrap-producing units. It is mistakenly believed by most people that the best results can be obtained by the elimination of automobile dumps. But in view of the fact that anywhere from a million to two and a half million cars come off the roads annually to enter graveyards, it is essential that such places be kept in operation as an important continuing source of scrap metal supply.

ADVERTISING IN A WARTIME ECONOMY

Watching advertisements may well be considered as important as watching scientific articles for the latest developments in the science of medicine. Especially now, when so many changes may occur in products or sources of products due to restrictions in materials or manufacture.

Even as it is essential for the producer to keep in touch with his market, so it is just as imperative that the consumer, or the prescriber, know what is still available and where it can be obtained. And don't depend entirely upon what may have been heard indirectly!

A recent incident of a rumor creating a wrong impression is the case of a manufacturer of appliances who found that somehow word had been passed around that he was out of business for the duration. He might have gone on blissfully losing business if a representative had not happened to call on one of the physicians who had heard "that this concern had closed up shop for lack of material and labor." Maybe the manufacturer was largely to blame for

not keeping his market sufficiently informed, and the physician may have been partly to blame for taking a casual remark at face value.

BUT—the real seriousness of skipping the advertisements is the ever-present possibility today of changes in formulas of pharmaceutical and biological products. Potencies may have to be changed and in some cases an ingredient may be omitted or substituted.

The producer has no intention of keeping you in the dark concerning such changes. If it is a material change, he wants you to know it and often his notification must depend on your seeing his advertisement.

Then, too, there may be a time when some item is needed in a hurry. If you know who is still able to supply it you may avoid the possibility of thinking you will have to get along without it.

Abnormal conditions connected with a military economy produce new and special advertising messages vital to continuing an efficient practice.

What could be a more sensible formula for the control of cough?—Thiocol to act as a sedative expectorant; codeine phosphate to inhibit the cough reflex and to produce a sedative effect; sodium citrate and citric acid to liquefy tenacious bronchial secretions; and chloroform to relieve throat tickle. These are the ingredients of Citro-Thiocol 'Roche.' In addition to its effectiveness in the control of even the most stubborn cough, Citro-Thiocol is pleasant tasting and appealing in appearance—a remedy in keeping with the pharmaceutical elegance of all Roche preparations. Supplied in 4-ounce, 1-pint, and 1-gallon bottles. HOFFMANN - LA ROCHE, INC., NUTLEY, NEW JERSEY.

Anemia and The Ides of March

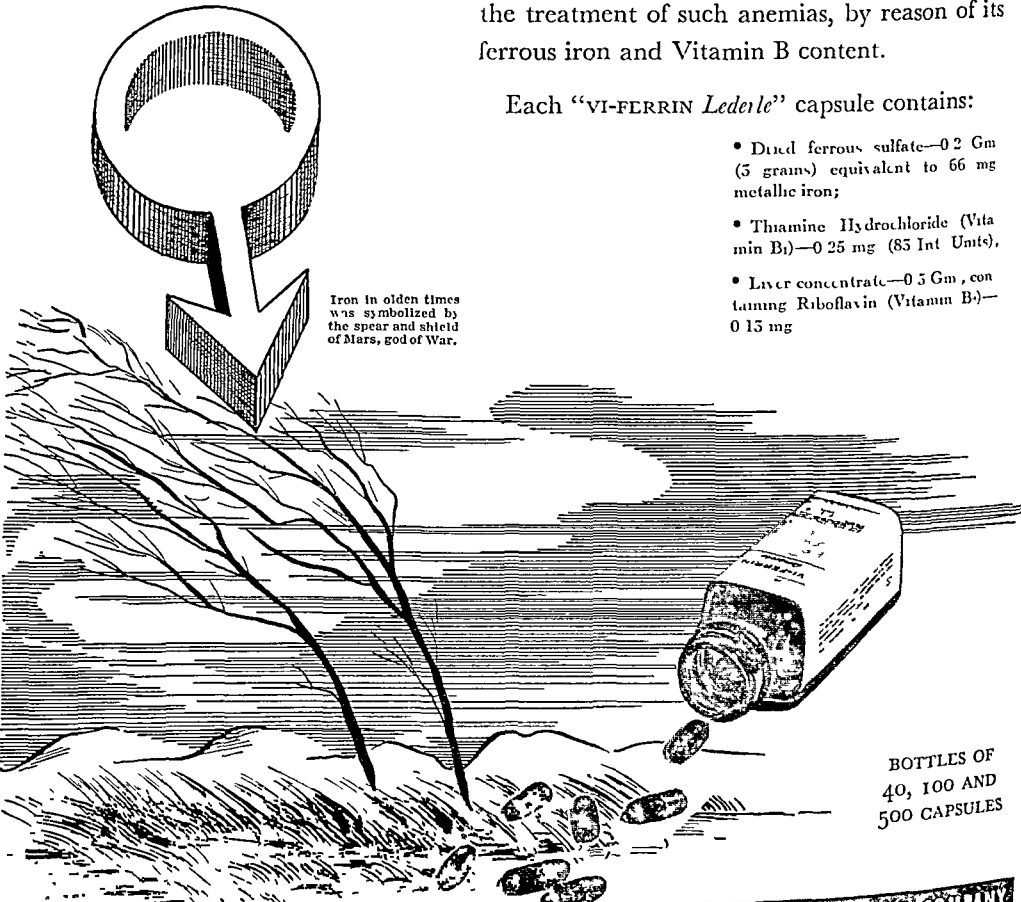

VI-FERRIN *Lederle*

SECONDARY ANEMIA follows closely the many respiratory and other infections so prevalent in early spring. Once the course of the infection has been arrested, treatment of the secondary anemia so frequently present should be commenced. This treatment should be directed not only toward hemoglobin regeneration, but also toward remedy of the dietary anorexia.

"VI-FERRIN *Lederle*" is particularly suited to the treatment of such anemias, by reason of its ferrous iron and Vitamin B content.

Each "VI-FERRIN *Lederle*" capsule contains:

- Dried ferrous sulfate—0.2 Gm (5 grains) equivalent to 66 mg metallic iron;
- Thiamine Hydrochloride (Vitamin B₁)—0.25 mg (85 Int. Units),
- Liver concentrate—0.5 Gm, containing Riboflavin (Vitamin B₂)—0.15 mg

Iron in olden times was symbolized by the spear and shield of Mars, god of War.

Give the cigarette they prefer to get*

IT'S EASY to understand why cigarettes are the preferred gift in the armed services. But did you know that among them the best-liked brand* of cigarette is Camel? Camel is the popular choice of millions and millions of smokers for its finer flavor and superior mildness.

Send Camels, the service man's favorite, to those friends or relatives who are fighting our battles —fighting them efficiently and unselfishly. Your thoughtfulness will be appreciated.

Tobacco stores feature Camels by the carton. See or telephone your dealer today.

Remember, you can still send Camels to Army personnel in the U.S., and to men in the Navy, Marines, or Coast Guard *wherever they are*. The Post Office rule against mailing packages applies only to those sent to the overseas Army.

* With men in the Army, the Navy, the Marine Corps, and the Coast Guard, the favorite cigarette is Camel. (Based on actual sales records in Post Exchanges and Canteens.)

Camel

costlier tobaccos

Anemia and The Ides of March

VI-FERRIN *Lederle*

SECONDARY ANEMIA follows closely the many respiratory and other infections so prevalent in early spring. Once the course of the infection has been arrested, treatment of the secondary anemia so frequently present should be commenced. This treatment should be directed not only toward hemoglobin regeneration, but also toward remedy of the dietary anorexia.

"VI-FERRIN *Lederle*" is particularly suited to the treatment of such anemias, by reason of its ferrous iron and Vitamin B content.

Each "VI-FERRIN *Lederle*" capsule contains:

- Dried ferrous sulfate—0.2 Gm. (3 grains) equivalent to 66 mg. metallic iron;
- Thiamine Hydrochloride (Vitamin B₁)—0.25 mg. (85 Int. Units);
- Liver concentrate—0.5 Gm., containing Riboflavin (Vitamin B₂)—0.15 mg.

THE ORIGINAL DEHYDROCHOLIC ACID

Decholin — chemically pure dehydrocholic acid — initiated a new era in salt therapy. Prior to 1929, therapy was restricted to desiccated bile mixtures of variable composition and of uncertain therapeutic action.

Decholin prompted an imposing chain of research studies on the physiology and pathology of the gallbladder, bile ducts, and the liver. Of the 408 original research investigations on the clinical value of dehydrocholic acid, all are based on Decholin.

Decholin is the most potent hydrocholeretic available. It increases elaboration of bile as much as 200 per cent, affording a valuable means of flushing the biliary passages. The toxicity of Decholin is lower than that of any other known bile acid, so low that its sodium salt, Decholin sodium, is given intravenously. Decholin is contraindicated in complete obstruction of the hepatic or common bile duct.

nascent OXYGEN for LEUKORRHEA

CLINICALLY TESTED*: (a) eliminates unpleasant odor of discharge; (b) cuts down or eliminates irritations inside and without the vagina; (c) reduces quantity and density of the discharge, including that following cauterization... Non-irritating and non-toxic in contradiction to the arsenic and picrate preparations, is equally effective and actually soothing, especially in the (a) infantile vagina, (b) senile vagina, (c) trichomonas vaginalis vaginitis of pregnancy.

*Barrows: N. Y. St. Jr. Med. Vol. 41, 1/15/41

nascent OXYGEN for DRESSINGS

CLINICALLY TESTED*: As a surgical dressing: gauze, saturated with STA-O-GEN (a) does not adhere to wounds, (b) reduces discharge, (c) eliminates unpleasant odor, (d) wounds heal faster and appear healthier, (e) dressings are easily applied, continue effective longer and cause no burning or pain when changed, (f) there is no irritation of the skin about the wound edge, (g) particularly effective around perianal region in post-operative work (h) stainless.

*Cowett: Meet, N. Y. Proc. Soc. 4/15/42

STA-O-GEN is a bland ozonide of olive oil. On application, it releases nascent oxygen continuously for hours—deodorizing, germicidal, fungicidal, healing. Available in Liquid or Ointment; also Vag-I-Caps for leukorrhea prescription. For your convenience, druggists may obtain from any jobber.

Advantages
of ELIXIR
Bepadin**

Each fluid ounce contains:

Thiamine Hydrochloride (Vit. B1)
1000 U.S.P. Units
Riboflavin (Vit. B2) 2000 Micrograms
Niacin Amide 18.5 Milligrams
Pantothenic Acid 2000 Micrograms
Pyridoxine Hydrochloride (Vit. B6)
1000 Micrograms

PLUS

DEMONSTRABLE quantities of:

Biotin
Inositol
Choline
Para-aminobenzoic Acid
Folic Acid

As found in Yeast Concentrate, Liver
Concentrate and Rice Bran Extract
combined in a PALATABLE Sherry
Wine Base.

High Potency **ELIXIR**
B-COMPLEX Containing 1
better known, lesser known
and unidentified factors
the **VITAMIN B-COMPLEX**
at a saving to your patient

Physicians have found that most vitamin B deficiencies are multiple and require the *COMPLETE* B-Complex for fully effective treatment.

Elixir Bepadin combines the *NATURAL* B-Complex factors found in Liver Concentrate, Yeast Concentrate, Rice Bran Extract together with added synthetic vitamin materials in Sherry Wine. The exceptionally pleasant flavor of the Sherry Wine Base overcomes objectionable taste which are often associated with preparations containing yeast or liver.

By prescribing Elixir Bepadin you can be sure your patient will receive a balanced dosage of all the factors *synthesized, identified and unidentified* of the Vitamin B-Complex.

Elixir Bepadin is available at all better drug stores in 16-oz. bottles.

I. V. C. confines its efforts exclusively to the production of effective vitamin preparations. 25 I. V. C. preparations bear the seal of acceptance of the Council on Pharmacy and Chemistry of the American Medical Association.

Elixir Bepadin is a development of our laboratory and incorporates the findings of long, exacting research.

Members of the medical profession by the thousands have already requested literature and samples of Elixir Bepadin. May we here thank them for their enthusiastic acceptance of this product.

Write on your letter head today for FREE professional literature and samples of Elixir Bepadin.

NUTRITION RESEARCH LABORATORIES
CHICAGO

ETRON*

Eliminate Foci Relieve Pain

Cumulation of clinical experience in arthritis treatment reveals that a well-planned course of therapy is desirable in all cases.

In conjunction with the administration of ETRON, it is usually advisable to provide analgesic medication, particularly in the early stages. Chronic foci of infection should be eliminated where possible. Physical therapy is often useful.

Even in high dosage, ETRON is not incompatible with measures aimed at relief of pain or correction of exciting factors.

ETRONIZE THE ARTHRITIC PATIENT

The technic of *Ertronzation* employed by various authors is practically identical. All agree that a dose of six capsules of ETRON a day should be maintained throughout the entire course of treatment, if possible. This high dosage is attained by gradually building up from an initial dose of two or three capsules daily.

A file card containing dosage suggestions in detail is available to interested physicians.

When depression accompanies more fundamental pathology

In many patients, depression may occur as an accompaniment of some more fundamental pathology, either organic or psychogenic. In such cases, the physician should bear in mind that, while Benzedrine Sulfate will not affect the underlying condition, its stimulatory effects may help to alleviate the concomitant depression which so often interferes with the management of the case.

Benzedrine Sulfate Tablets

Brand of amphetamine sulfate

Benzedrine Sulfate is primarily useful in depressions characterized by apathy and psychomotor retardation, but is contraindicated in patients manifesting anxiety, hyperexcitability, or restlessness.

The use of Benzedrine Sulfate by normals should not be permitted; it should always be administered under the careful supervision of a physician; and depressive psychopathic cases should be institutionalized.

In treating depressed patients with Benzedrine Sulfate, the physician should bear in mind that any drug which produces pleasant or euphoric effects may prove to be habit forming—especially in unstable or neurotic individuals.

FOR SECONDARY AND NUTRITIONAL ANEMIA . . . Use Elixir **VITA-LIV-FERIN**

Each Fluidounce Represents:

Thiamine Hydrochloride (B-1)	8 mg
Iron & Manganese Peptonized	30 gr
Nicotinic Acid	25 mg
Fresh Liver	3 oz
Representing	
Riboflavin (B-2)	1,000 gamma
Pyridoxin (B-6)	230 gamma
Pantothenic Acid	2,200 gamma
Filtrate Factor	q s

Containing adequate doses of Iron, Vitamin B Complex factors and the anti-anemic principles of Liver, Vita-Liv-Ferin is suggested in cases where the regeneration of hemoglobin is required, as well as promoting growth of children, aiding digestion, stimulating the appetite and as a general nutritional tonic

Vita-Liv-Ferin is miscible with water, milk or fruit juices. This palatable tonic does not nauseate nor disturb the gastric region neither does it constipate or promote diarrhea

FOR COMPLICATIONS AS OLD AS TIME

This interesting study of fetal circulation is taken from Antonin Bossu's *Anthropologie Etude des Organes, Fonctions, Maladies de l'Homme et de la Dame* published in Brussels in 1847.

IF NEED for stimulation of labor arises in delivery rooms, obstetricians often rely upon Pitocin*, an oxytocic of many advantages and dependable performance.

Pitocin consists of the oxytocic principle of the posterior pituitary gland with practically none of the pressor hormone. Its extremely low protein content so minimizes possibility of systemic reaction that many physicians prefer Pitocin for routine management of obstetric patients.

Pitocin is indicated for stimulation of uterine musculature in uncomplicated obstetrics, increasing tone of the uterus by direct action. It is widely used in uterine inertia during the second stage and to check uterine hemorrhage.

The Popularity of

THESODATE (*Brewer*)

(the original enteric-coated tablet of Theobromine Sodium Acetate)* is due to three factors:

1. IT IS CLINICALLY PROVED.
2. IT IS EFFECTIVELY ENTERIC COATED.
3. IT IS DECIDEDLY LESS EXPENSIVE.

Indicated in treatment of coronary artery disease, edema and hypertension.

Dosage: One 7½-grain tablet four times a day, before meals and upon retiring.

Available on prescription in 7½-grain tablets, with or without Phenobarbital (½ grain), or 3¾-grain tablets, with or without Phenobarbital (¼ grain), and Theobromine Sodium Acetate 5 grs. with Potassium Iodide 2 grs. and Phenobarbital ¼ gr., 100 per bottle.

* Capsules are now available for those few patients who need extra medication.

CLINICAL VALUE OF MUSCLE EXTRACT

Carnacton *in*

**ANGINA PECTORIS ARTERIOSCLEROSIS
OBLITERATIVE ARTERIAL DISEASES**

Carnacton is a biologically tested extract of *diaphragm muscle* — a powerful, markedly vascularized muscle with a high metabolic rate — most effective for its purpose. Carnacton is not only a vasodilator but also promotes cardiovascular tone and vigor.

In 1 cc. and 2 cc. ampuls — boxes of 12 and 50; vials of 30 cc. for oral use. Send for professional brochure.

CAVENDISH PHARMACEUTICAL CORP., 25 West Broadway, New York

“WAR HAS REVEALED THE UNSUSPECTED COMMONNESS OF PEPTIC ULCER”*

In the medical records of the countries at war one disease outnumbers all others in the field of digestive disorders. *Peptic ulcer.*

Chamberlin reports that 98 out of 316 patients admitted to the gastro-intestinal section, Lawson Gen'l Hospital, Atlanta, Ga., and 49 out of 113 at Tilton Gen'l Hospital, Ft. Dix, N. J., had proven peptic ulcer.**

In England 14.2% of men discharged from the army during a given period had peptic ulcer; 54% of them after less than 12 months service.*

This situation is a challenge to which CREAMALIN, brand of aluminum hydroxide gel, is bringing great accomplishment. CREAMALIN was the first aluminum hydroxide gel to be made available and the first to be Council-accepted.

*Brockbank, Wm.: The Dyspeptic Soldier. Lancet, Jan. 10, 1942.

**Chamberlin, D. T.: Peptic Ulcer and Irritable Colon in the Army, Jnl. D. D., Aug., 1942.

WHAT CREAMALIN OFFERS

- ▶ Pronounced and prolonged antacid action of 12 times its volume of N/10 HCl in less than 30 minutes (Toepfer's reagent)
- ▶ Non-alkaline; non-absorbable; non-toxic
- ▶ No acid rebound; no danger of alkalosis
- ▶ Prompt and continuous pain relief in uncomplicated cases
- ▶ Rapid healing when used with regular ulcer regimen
- ▶ Mildly astringent; may reduce digestive action, thus favor clot formation
- ▶ Demulcent; gelatinous consistency affords protective coating to ulcer
- ▶ Approximately 5.5% aluminum hydroxide

to reduce industrial absenteeism due to urinary infections

In the vital battle of production, it is essential that every worker be kept on the job and at full production capacity.

When a war worker suffers with one of the common urinary infections, Pyridium is of decided service. This is especially evident in the milder, ambulant cases of urinary infection.

The prompt and effective symptomatic relief provided by Pyridium contributes to a more rapid recovery, with the result that the worker can be returned to his job sooner than would otherwise be possible.

Pyridium is convenient to administer. The average oral dose is 2 tablets t.i.d. At this dosage level, it possesses the combined advantages of relative nontoxicity, effectiveness in the presence of either acid or alkaline urine, and local analgesic effect on the urogenital mucosa.

BACK HOME AT 4 . . .

AND WITH AN APPETITE

For the normal as well as the undernourished child, a tasty between-meals' snack of Horlick's Fortified offers an excellent tide-over to the next full meal.

Instead of loading up with appetite-destroying confections or sweet drinks of poor food quality, why not let them benefit from the basic, nutritive and protective elements found in Horlick's.

HORLICK'S FORTIFIED

provides rich protein, carbohydrate and fat in balanced proportions, calcium and other essential minerals, together with maintenance doses of A, B₁, D and G.

Moreover, Horlick's is partially predigested, homogenized, has negligible curd tension and, therefore, leaves the stomach rapidly enough to avoid destroying appetite for the next full meal.

ABOUT CLAIMS

vs. ACTUAL DIFFERENCES

in cigarettes

WHAT value can claims of superiority in a cigarette have unless there is a difference in formula or process to justify that claim?

PHILIP MORRIS Cigarettes are made differently. In the clinic as well as in the laboratory, the *advantages* of PHILIP MORRIS have been repeatedly observed, repeatedly reported by recognized authorities in leading medical journals. Yes, PHILIP MORRIS *claim* superiority . . . and that superiority has been proved.*

With the current increase in smoking, may we suggest that it is more important than ever for your patients suffering from irritation of the nose and throat due to smoking to change to PHILIP MORRIS—the one cigarette proved definitely less irritating.

For Cleansing Soap-Sensitive Skins **ACIDOLATE**

TRADE MARK REG. U. S. PAT. OFF.

PROVIDES the thorough cleansing properties of selected sulfated vegetable oils—in combination with a non-irritating mineral oil which lessens any tendency toward skin dryness.

Acidolate is completely soluble in water. It can be quickly washed from hair or skin surfaces. Skin cleansed with Acidolate is left with a feeling of soft coolness.

The usefulness of Acidolate as an aid in the management or prevention of skin irritations has been demonstrated by properly controlled clinical tests.*

Complete literature will be sent to doctors on request.

FEAR OF THE UNKNOWN

• Fear or extreme apprehensiveness are conditions that must be dealt with in the majority of surgical patients, especially the younger ones, and for this reason preoperative sedation is generally a desirable measure. 'Delvinal' Sodium Vinbarbital Sodium has proved exceptionally useful for this purpose, inducing a *smooth* transition from tense wakefulness to restful quiet and sleep.¹

When 'Delvinal' Sodium is administered preoperatively, the amount of anesthetic may be reduced by one-quarter or one-third, and the incidence of vomiting is lowered.² Moreover, by means of 'Delvinal'

Sodium, amnesia and rest may be obtained postoperatively, and other advantages associated with the use of this preparation in surgical anesthesia are economy of time and opiates.

'Delvinal' Sodium is also indicated for the relief of functional insomnia and various psychiatric conditions, as well as for obstetric sedation and amnesia.

Supplied in dry-filled capsules of three strengths: $\frac{1}{2}$, $1\frac{1}{2}$ and 3 grains.

Irrigating THE GALL BLADDER TO OVERCOME STASIS

Ketochol, one of the many outstanding Searle Research developments, exerts a "flushing" action in the gall bladder and bile ducts by promoting the secretion of thin, free-flowing bile by the liver.

The entire biliary tract is thereby drained non-surgically, stasis is overcome, and congestion is materially reduced.

Ketochol is a combination of the oxidized or keto form of those bile ACIDS (cholic, desoxycholic, chenodesoxycholic and lithocholic), normally present in human bile. In the oxidized form they are relatively non-toxic.

INDICATIONS

Cholecystitis (chronic, subacute), cholangitis, hepatitis, cirrhosis.

AVERAGE DOSE:

1 or 2 Ketochol tablets 3 times daily.

HOW SUPPLIED:

Bottles of 100 and 500 tablets.

VOLUME 43

MARCH 1, 1943

NUMBER 5

Editorial

Annual Meeting, 1943

The Convention Committee of the Council is now able to announce that arrangements for the 137th Annual Meeting of the Medical Society of the State of New York are progressing most satisfactorily. The place, as previously announced, is the Hotel Statler in Buffalo. The meeting will open on Monday, May 3, and continue through May 6.

The keynote of the scientific meeting will be "War Medicine and Surgery." Not only will papers of the general and section programs stress the newer things in the scientific and general practice field, but also exhibits are being planned which will show dynamically the many varied aspects of medicine's wartime needs, for the civilian population as well as for the fighting forces. The Office of Procurement and Assignment will have a booth on the seventeenth floor, where Dr. J. R. Clemmons and Dr. McGill Burns will be prepared to answer any and all questions concerning the medical manpower situation in this state.

This year there will be several new procedures. First, the annual banquet will not be held. The Convention Committee of the Council, wishing to cooperate with the government's request for maximum food conservation, has proposed this omission from our usual procedure. At the time that the banquet would have been held, namely Tuesday evening, May 4, there will be a dinner meeting of the Chiefs

of Emergency Medical Service of the counties of the state, or their deputies. This dinner meeting is being held at the suggestion of the OCD. Col. George F. Baehr will give an address and will act as chairman of the meeting. Questions from the floor will be in order.

The Convention Committee is seeking to prepare a program specifically directed at the needs of the physicians of the state who are responsible for their communities' health. It is anticipated that with men returning from all parts of the world, tropical disease will become a factor in the health of many communities. Every physician who attends will be enabled to acquire information on war medicine and surgery, on tropical diseases, on industrial medicine and surgery which is more recent and up to date than that which he can get from any textbook. It is therefore to the interest of every community in the state to have its available doctors attend this annual meeting. After having done so, they will go back to their community better informed and better prepared to care for their patients' health and thus to contribute maximally, through the improvement of general health in their locality, to the health of the nation.

Other scientific exhibits will cover the subjects of shock, the blood plasma program, war gases, tropical diseases, tuberculosis, and first aid for doctors.

Note the dates of the meeting *now*.

See important notice on page 420

Venereal Disease

In 1942, the rate of prevalence of syphilis in the entire male population of the United States between the ages of 21 and 35 was estimated to be 47.7 per thousand, based on serologic blood test reports of 1,895,778 white and Negro men, who, according to Vonderlehr and Usilton, were tested under the provisions of the Selective Training and Service Act of 1940.¹ The rate of prevalence in the entire male population 21 to 35 years of age, from rural areas, is 49.4 per thousand, and from urban areas, 46.5 per thousand.

What are the facts for the State of New York? Dr. Edward S. Godfrey, Jr., Commissioner of Health, reports for the state exclusive of New York City "that there has been an increase of 9.7 per cent in case reports received for early syphilis for patients of all ages during 1942 as compared with 1941. In the age group of 15 to 19 years, case reports were received to a number 38.9 per cent greater than in 1941. On the same basis of comparison, primary and secondary syphilis increased 54.3 per cent and 16.7 per cent, respectively. These figures appear to be significant, inasmuch as the downward trend in case reports for syphilis has been generally reversed for the first time in our experience of six years of complete case reporting."²

"A 'serious rise' in venereal disease was noted in 1942, according to the annual report of the city health department. For the first eleven months of the year there were 28,068 cases of syphilis recorded, an increase of 13 per cent over the corresponding period for 1941. A total of 11,208 cases of gonorrhea was reported, with the number of unreported cases thought to be many times greater, according to the *New York Times*. Neither venereal disease nor any other vital statistics of service men on duty are included in the city reports."³

New York City Department of Health figures for eleven months of 1942⁴ show for early syphilis in the 15-to-19-year group an increase of 44 cases reported over 1941, and for the age group of 20 to 24 an increase of 137 cases. For all stages of syphilis the 15-to-19-year group shows an increase

of 117 cases, the 20 to 24 group an increase of 52 cases. In New York City, from 1938 through 1941, the trend for early syphilis—all ages—has been downward, 1941 being 41.5 per cent below 1938. For all stages of syphilis, case reports in 1941 were 26.7 per cent below those reported in 1938. Reported cases, in both early and more advanced stages, for the eleven months of 1942 show a slight numerical increase over 1941. Thus the trend seems to be decidedly upward in the entire state since 1941.

For what reasons was the trend downward for five years? Why has it particularly increased for the 15-to-19-year group during the last year? Conditions arising from the war as they affect the family and the individual may in some measure be responsible, but in what measure? The national picture of 47.7 per thousand serologic positives in the age group of 21 to 35 in 1942 is not encouraging. The state picture for the 15 to 24 group, which shows an increasing number of infections in the young, is no better.

What can be done about it? Current agitation for the better conservation of manpower and woman power should make these trends in the incidence of venereal disease of paramount interest to the medical profession as well as to the government.

The Health Commissioner of New York City, recognizing the seriousness of the rise in venereal disease incidence, requested high-school instruction in social hygiene.

"The Board of Education has granted permission to the City Department of Health to use four schools to give pre-induction training courses on Saturday mornings. The Board of Education had refused to include such a course in the regular curriculum. In a letter to the Health Commissioner, Ernest L. Stebbins, John E. Wade, deputy superintendent of schools, wrote that, should the health officials decide to organize these classes, 'the Board of Education will not identify itself in any way with your proposals and we will not be in any position to advertise the lectures to the students; we will make

available premises to you as we would to any other organization, but you must undertake the enterprise as a project of the Department of Health wholly unrelated in any way to the Board of Education.' The request for high-school instruction in social hygiene was made by Dr. Stebbins because of a 20 per cent increase in venereal infection among boys and girls 15 to 19 years old. In granting permission to use the schools, the Board stated that any legitimate organization had the right to use the schools on Saturday mornings provided the facilities were available."⁵

It is certain that the problem of a rising incidence of venereal infection in young

persons will not solve itself! Nor can it be ignored. It seems evident that it must be combated largely by educational methods of some kind, but as yet the technics of such methods have not been worked out. Here appears to be an opportunity for physicians, educators, specialists in public health, and government to establish, in collaboration, an effective method to combat what appears to be a growing menace to the public health.

Accidents in the Home and on the Farm

The National Safety Council estimates that home accidents result in an annual economic loss of about \$600,000,000. Furthermore, home accidents are responsible for about 34.5 per cent of all fatalities and for 53 per cent of all disabling injuries resulting from accidental causes. There is danger that in emphasizing the industrial health programs and industrial accident prevention it may be forgotten that about 61 per cent of deaths and injuries to industrially employed persons occur while they are not at work, and in a large proportion while they are at home.

That personal health plays an important role in accident prevention is recognized in the New York State program on Home and Farm Safety set up by the New York State Department of Health. A committee on Personal Health and Safety has been suggested by the National Safety Council, under whose impetus the New York State program is proceeding. The general chairman of the New York State program, B. R. Rickards, Director of the Division of Public Health Education, has named chairmen of the ten committees. Dr. J. G. Fred Hiss is chairman of the committee on Personal Health and Safety. Other phases of the program call for the cooperation of architects and builders, agricultural engineers, household equipment manufacturers and dealers, landscape architects, public

health nurses, teachers, and other professionally trained personnel in a position to contribute to home safety. The interest of a large number of state organizations has also been obtained. These organizations plan programs of study for their respective memberships, and many of them will participate in community education as well.

Outstanding among the organizations, in addition to the State Medical Society and State Nurses' Association, are the State Grange, the State Federations of Home Bureau, Farm Bureau, and 4-H Clubs, the State Congress of Parents and Teachers, the State Federation of Women's Clubs, the American Legion, and many other groups.

The program of education is advancing along many important fronts, with a special contribution to the public interpretation of the work coming through the Governor's proclamation on Labor Day, which was followed by a series of newspaper releases and radio talks promoted by the State and Local War Councils.

Facilities for educational interpretation are being developed. The American Red Cross will provide instructors for a nine-hour course in Home Safety, with certificate granted upon completion of the study. The Metropolitan Life Insurance Company, Travelers Life Insurance Company, John

Hancock Life Insurance Company, and other insurance companies have developed literature, exhibits, motion pictures, and other helps. The State Department of Health has twenty panel exhibits for loan to communities and soon will have a talking slide film. Physicians are urged to cooperate in this program by calling attention

to accident hazards in the homes that they visit, by assisting on committees, and by giving talks. An outstanding contribution by physicians will be in recognizing personal health conditions that might induce accidents and in warning the individual or family of the situation so that additional precautions may be taken.

Dear Sir:

Will you please publicize the fact that the Arbitration Headquarters of the New York Area has

moved from 125 Park Avenue to the adjoining building at 110 East 42nd Street, room 1213; telephone number Lexington 2-2354.

Arbitrations for the five counties of the metropolitan area will be held at the above headquarters from this date.

Very truly yours,

DAVID J. KALISKI, M.D., *Director*

THE DIFFERENTIAL DIAGNOSIS OF HYPERPARATHYROIDISM WITH ESPECIAL REFERENCE TO ALBRIGHT'S SYNDROME

L. W. GORHAM, M.D., Albany, New York

THE differential diagnosis of hyperparathyroidism may be difficult, even though the history and roentgenograms in a particular patient with chemical and biopsy studies may point strongly to this diagnosis. As is well recognized, a hyperfunctioning parathyroid gland containing an adenoma produces a widespread decalcification of the skeleton, leading to the condition known as generalized osteitis fibrosa cystica (von Recklinghausen's disease). Hyperparathyroidism is insidious in onset, more often affecting women than men, with the greatest number of cases occurring in midlife. The symptoms are numerous and variable. Most common are bone and joint pain, pathologic fractures, muscle weakness, disturbances of gait, and, late in the disease, marked deformities of the bones. In a smaller number of cases renal and gastrointestinal symptoms appear, such as polyuria, polydipsia, renal colic, anorexia, nausea, vomiting, epigastric pain, and marked loss of weight. The chemical changes in calcium and phosphorus metabolism produced by the increased activity of the parathyroid glands are quite characteristic. Under normal conditions these small glands regulate the metabolism of calcium and phosphorus in the body within rather narrow limits, maintaining the level of blood calcium at 9.5 mg. to 11 mg. per cent, and the blood phosphorus at 3 mg. to 4.5 mg. per cent. With the onset of hyperparathyroidism, calcium is withdrawn from the bones, the blood phosphorus level falls, and the blood calcium rises sharply. The excretion of both calcium and phosphorus in the urine is also increased. The blood phosphatase is usually increased, indicating a rise in new bone production. The normal figures for phosphatase are 1.5 to 4 Bodansky units in adults. The constant drain upon the skeleton with calcium loss leads to pathologic bone which is soft, pliable, and readily fractured. The x-ray films show a general decalcification, with thinning of the cortex and trabeculae of the long bones. The skull appears finely granular, and there may be apparent cyst formation in the shafts of the bones. Operation and autopsy have shown that what appear to be cysts by x-ray are actually areas of fibrous tissue replacing bone.

Von Recklinghausen, in 1891, described 3

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 30, 1942

From the Department of Medicine, Albany Medical College Union University, Albany, New York

cases of fibrous osteitis, and his name has since been attached to the disease. Although various authors had suspected the relationship of parathyroid tumor to von Recklinghausen's disease, it was not until 1925, when Mandl¹ successfully removed one of these tumors with marked benefit to the patient, that its true significance and importance were established. The first case to be recognized in the United States was studied by Dr Eugene F. Dubois² in 1926. The old sea captain, Martel, required seven operations before the parathyroid tumor was finally located in the anterior mediastinum. Barr, Bulger, and Dixon³ reported the first proved case in this country in 1929. Since then a large number of cases have been described, Wilder and Howell⁴ being able to collect 135 undoubted examples from the literature in 1936. In June of that same year a patient was admitted to the Albany Hospital who illustrates the first and most important condition to be differentiated from hyperparathyroidism.

Case Report

History—Mrs. G. R., 25 years old, a laundry worker, complained of pain and swelling in the left forearm, attributed to an injury in November, 1935. Past history was noncontributory except that in 1930 she suffered a fracture of the right femur, at which time an x-ray diagnosis of osteitis fibrosa cystica is said to have been made. Examination showed slight deformity of the left forearm with swelling in the region of the upper portion of the radius. The left humerus felt thickened. The right femur was bowed anteriorly and externally, and there was a shortening of the right leg of $\frac{3}{4}$ inch. The right tibial shaft was palpably thickened. There was a pigmented spot on the left buttock, the presence and significance of which was not realized until later when the patient was seen by Dr. Fuller Albright.

The roentgenographic examination of the skeleton showed marked changes involving the left radius, the left humerus, the metacarpal bone of the left index finger, the fifth rib on the left side, the right ilium, left ilium, left ala of the sacrum, the superior ramus of the left pubis, the inferior ramus of the right pubis, the tuberosity of the right ischium, the right femur, and the right tibia.

Laboratory Data—The urine was negative. Bence-Jones protein was not present. The Wassermann reaction was negative. The blood count was normal. Blood calcium was 13.5 mg., 11.5 mg., and 10.4 mg.; blood phosphorus, 5.2 mg., 7 mg., and 3 mg.; blood phosphatase, 7.4 Bodansky units. Biopsy of the fifth left rib was reported as showing typical osteitis fibrosa. Although the blood calcium

was found to be elevated only once out of three examinations and although the blood phosphorus was never below 3 mg. per cent, it was felt that with such suggestive x-ray and biopsy findings the patient was entitled to exploration of her neck for the removal of a possible adenoma of the parathyroid. Operation was performed by Dr. Eldridge H. Campbell on July 22, 1936. The four parathyroids were located and examined, but no adenoma was found. The upper right parathyroid was considerably larger than any of the other three glands. This was removed but showed no signs of tumor on histologic examination. Some months later Dr. Fuller Albright saw the patient at my request and pointed out the small area of pigmentation on the buttock. He stated that he had seen several cases with osteitis fibrosa, skin pigmentation, and precocious menstruation, which had been confused with hyperparathyroidism. Our case apparently fell in this group, although there was no history of sexual precocity. The patient was of Nordic stock, however, and the menses had begun at 14 years, while those of her mother and sister had begun at 18 years. The patient gave birth to twins in February, 1937, and in May, 1941, the mother and both children were examined. The children showed no signs of osseous disease by x-ray and no skin pigmentation, while their mother's condition remained unchanged.

In 1937 Albright⁵ and his associates described 5 cases and, in 1938, 2 more⁶ which showed the bizarre combination of three apparently unrelated features, viz. (1) osteitis fibrosa cystica, (2) brown pigmented skin spots, and (3) precocious puberty (particularly in females). Three of these patients had been operated upon in other hospitals in a vain search for parathyroid adenoma. In reviewing the literature one finds that at least seven examples of this syndrome had been reported in females and five in males before Albright's paper was published. The precocious puberty, however, was lacking in the males. The first example of this curious condition was described by Weil⁷ in 1922 before a medical society meeting in Breslau. The patient was a 9-year-old girl who had begun to menstruate at the age of 1½ years, had suffered eight fractures, revealed the secondary sex characteristics of a girl of 15 years, showed by x-ray scattered bone changes with precocious bone development, and had abnormal pigment deposits in the skin. Weil thought he was dealing with a disturbance of the adrenal glands. Albright suggests that the syndrome is due to some neurologic or embryonic defect in the region of the hypothalamus. A total of 32 cases (16 females, 16 males), conforming to Albright's original description, has been recorded to date.⁸ Thirteen of these have been confused with hyperparathyroidism and were operated

upon but no tumor was found. Three of the patients were operated upon twice.

In addition to the 32 cases which conform to the picture described by Albright, there are to be found also 19 cases which possess one and occasionally two of the diagnostic criteria. These may be designated as the incomplete form of Albright's syndrome. Thus Salzer⁹ in 1933, Gaupp¹⁰ in 1932, and Borak and Doll¹¹ in 1934 reported cases with menstruation beginning at 2, 3, and 6 years of age with scattered cystic bone lesions but no pigmented spots. The case studied at the Albany Hospital showed bone lesions and skin pigmentation but no precocious puberty. The other 15 cases revealed neither precocious puberty nor abnormal skin pigmentation but have been reported as unilateral osteitis fibrosa, osteodystrophia fibrosa unilateralis, or as polyostotic fibrous dysplasia (Lichtenstein,¹² Jaffe¹³). In this group of 19 cases there are 7 in which fruitless exploration of the neck for parathyroid adenoma was performed. Two operations were performed upon one patient in this series.

It is evident, therefore, that a knowledge of this syndrome is most important in the differential diagnosis of hyperparathyroidism. Here is a condition in which in a total of 51 patients, there have been twenty useless operations, and, furthermore, 4 of these patients were operated upon a second time. Albright's syndrome is certainly the most important condition to be differentiated from hyperparathyroidism, as the record shows confusion arises in 40 per cent of the cases. The syndrome occurs in a complete and incomplete form. The disease starts in early childhood and nearly all victims of the complete type develop symptoms before the age of 10. In the incomplete form, patients may be 30, 40, or older before clinical manifestations appear. The disease is more frequent in females. While the x-ray appearance of the bones may be confusing, it should be emphasized that in Albright's syndrome the lesions are scattered, localized, and multiple, with considerable portions of the skeleton unaffected. This patchy distribution is in sharp contrast to the general decalcification of all osseous tissue found in hyperparathyroidism and osteomalacia and is more like Paget's disease and xanthomatosis. There is a tendency to unilateral involvement. Albright emphasizes three points in the roentgen examination of bones of the patients with this syndrome: (1) there are areas of increased density representing overgrowth of bone as well as decreased density; (2) there are parts of the skeleton that show normal bone; and (3) the epiphyses are rarely if ever involved. Biopsy specimens show osteitis

fibrosa with an absence of osteoclasts except in those cases which are rapidly progressive. In a few instances areas of cartilage have been found in specimens. There is a difference of opinion as to the relative value of the roentgen examination and bone biopsy in the differential diagnosis from hyperparathyroidism. Jaffe feels that the distinction can be made by microscopic examination with unfailing regularity, while Albright believes that the roentgen examination is more dependable. The fact is that confusion has arisen in many instances with both methods of study, and neither can be called infallible. The presence of pigmented skin spots over the sacrum, buttocks, or upper back should at once arouse suspicion. These spots, due to an increase in melanin in the basal layer of the skin, may be so insignificant as not to be noted or they may be hidden by hair in the back of the scalp and neck, so that they are not seen until the part is shaved.

Sexual and somatic precocity are present with great regularity in the female afflicted with the disease and, if accompanied by skin pigmentation or bone lesions, these conditions should call Albright's syndrome to mind. This feature may, however, be absent in the female as well as in the male. Calcium and phosphorus determinations on the blood usually serve to distinguish Albright's syndrome from hyperparathyroidism, but occasionally confusion is caused by the occurrence of a blood calcium above 11 mg., and a blood phosphorus below 3 mg. Balance studies of calcium metabolism regularly show a negative balance with excessive output in the urine in hyperparathyroidism. Only an occasional case of Albright's syndrome shows increased excretion of calcium in the urine. The blood phosphatase level is often elevated, showing increased bone production, but it is not of much differential diagnostic value.

The second disease which may simulate hyperparathyroidism or Albright's syndrome is illustrated by the following case report.

Case Report

C. W. L., an 11-year-old school girl, was seen October 21, 1937. At the age of 6 she had a fall, since which time the right forearm has been bowed. At 8 years an optic nerve tumor was removed. At 10 she suffered a fracture of the left femur as a result of a fall. No sexual precocity was present, as the menses were still absent when she was 11. Examination showed bowing of the right forearm and numerous pigmented spots on the skin, measuring a few to several centimeters in diameter. The urine was negative, the blood count was normal, the blood calcium was 10.8 mg. and the blood phosphorus 6.5 mg. X-ray showed cystic bone changes in the lower ends of each femur. Per-

mission for biopsy of skin and bone was refused. This case was probably an instance of von Recklinghausen's neurofibromatosis. Dr. Albright reviewed the evidence and agreed with this diagnosis. There are still those who believe that Albright's syndrome is nothing more than von Recklinghausen's neurofibromatosis. Against this view is the fact that biopsies of the skin have never shown neurofibromata in Albright's syndrome, while they are always present in sections of the skin taken from von Recklinghausen's neurofibromatosis.

A third case in a 14-year-old boy who was thought to have giant cell sarcoma of the hip, or possibly hyperparathyroidism, was first seen in April, 1940. Since his eighth year he had had pain and disability in the right hip. He was operated upon at that time in another hospital and the tissue removed was diagnosed as giant cell sarcoma. Examination at the present time showed shortening of the right leg and a marked limp in walking. There was an area of brownish pigmentation in the gluteal region. X-ray examination showed cystic bone changes in the right femur, the right tibia and fibula, the first right metacarpal, the right humerus, and the tenth rib on the right side. The only cystic area on the left side was located in the first metatarsal bone. The blood calcium and blood phosphorus levels were normal (calcium, 9.4 mg., and phosphorus, 3.8 mg.). The blood phosphatase was 7.12 Bodansky units, a slight increase.

In addition to the three types of bone disease which have been mentioned—i.e., Albright's syndrome, von Recklinghausen's neurofibromatosis, and giant cell sarcoma—one must consider briefly a number of other conditions in the differential diagnosis of hyperparathyroidism. Paget's disease of bone is to be distinguished by the onset in the later decades of life, by the normal blood calcium and blood phosphorus, by the usually very high phosphatase, by the characteristic woolly appearance of the bones in the x-ray films in some areas, and by the mosaic-like structure of the biopsied bone. Multiple myeloma may cause scattered lesions in the bony skeleton which at first glance suggest hyperparathyroidism. In some cases the blood calcium is definitely elevated. The characteristic features of this condition are usually, however, a normal blood phosphorus, hyperproteinemia with reversal of the albumin/globulin ratio, Bence-Jones protein in the urine, a normal blood phosphatase, plasma cells in bone marrow puncture, and round, punched-out lesions in the skull which, seen by x-ray, are quite suggestive. Osteomalacia with increased calcium excretion and softening of the entire osseous system is a rare disease and occurs with diets deficient in calcium and vitamin D. Repeated pregnancies are the commonest cause, although poor nutrition under war conditions has been reported as "hunger osteomalacia." The serum calcium is normal as a rule, although Albright states that it occasionally may be high because of a secondary parathyroid hyperplasia. The blood phosphorus is normal or low. The

phosphatase may be slightly increased and occasionally markedly elevated. Cystic areas by x-ray are not seen. Adolescent rickets like hyperparathyroidism leads to general demineralization of the skeleton. It occurs at a younger age than hyperparathyroidism and is further differentiated by the normal blood calcium, the normal to low blood phosphorus, the very high phosphatase activity, and the lack of cystic areas in the roentgenograms of the bones. Metastatic cancer involving bones, with hidden primary source, may occasionally show a high blood calcium, but confusion with hyperparathyroidism should not arise. Roentgenograms of the skeleton in cancer will invariably show certain bones which are entirely normal, while in hyperparathyroidism all of the bones are affected to some degree. Senile osteoporosis has been mistaken for hyperparathyroidism but should be differentiated by the normal values for blood calcium, phosphorus, and phosphatase. Multiple hemangiomas of bone, recently described by Pierson, Howard, and Farber,¹⁴ may produce widespread osteolytic lesions of the skeleton but are readily differentiated by biopsy as well as by other features. There are two unilateral lesions of bone which have been confused with Albright's syndrome but which should be easy to distinguish from hyperparathyroidism. These are Ollier's disease, known as unilateral dyschondroplasia, in which multiple enchondromas are limited to one side of the body, and xanthomatosis, a condition characterized by high blood cholesterol

and typical foam cells in the biopsy of affected bone.

In conclusion it may be said that of all the diseases of bone which may resemble hyperparathyroidism, Albright's syndrome is the most important. In a series of 51 published cases of the complete and incomplete variety, no less than 20 have been operated upon without finding an adenoma in the parathyroid and 4 of these patients were subjected to a second futile exploration.

RED CROSS DRIVE BEGINS MARCH 1

In what is expected to be the greatest philanthropic drive ever conducted in New York City, 100,000 volunteers will begin a house-to-house canvass March 1 to raise funds for the Red Cross. The quota for New York City is \$12,920,700, or 10.3 per cent of the national goal.

Chairman of the local drive is Colby M. Chester, with Walter S. Gifford serving as national chairman.

Officials of the campaign estimate that a minimum of two million contributions will be needed to meet the quota.

ABSTRACT OF MEDICAL ARTICLES BEING SENT TO DOCTORS IN SERVICE

Two projects that are aiding physicians in the armed forces not only to maintain professional competence in matters pertaining to military medicine but also to return to civilian practice at the end of the war armed with the latest knowledge in all fields of medicine, are announced in the *J.A.M.A.* for January 23.

The *Journal* says that: "By cooperation of the editorial staff of the *J.A.M.A.* with the Committee on Information of the Division of Medical Sciences of the National Research Council and the Divisions of Publications of the United States Army and Navy Medical Departments and the United States Public Health Service, a letter is being prepared every two weeks, which is distributed to every officer in these services. . . . The letters consist of from four to

six pages of brief abstracts of articles of significance appearing in the current medical literature.

"By special arrangement also E. R. Squibb and Sons has planned to distribute to officers in the armed forces a publication called *Medical Journal Abstracts*, prepared by the library staff of this company. . . . The company also offers to send *Medical Journal Abstracts* on receipt of a correct APO address to medical officers overseas, subject, of course, to decisions of governmental authorities in charge of postal regulations.

"Certainly these attempts to aid physicians in the armed forces to keep abreast of advances in medical science can result only in improvement in medical service to the men for whose health and medical care they are responsible."—*A.M.A. News*, January 21

SYPHILIS AS A CAUSE OF DELAYED PNEUMONIC RESOLUTION

JOSEPH F. WORTHEN, M.D., and MICHAEL S. RAPP, M.D., Staten Island, New York

THAT syphilis predisposes to the complications of lobar pneumonia, and especially to delayed resolution, has been advanced by Fitz-Hugh¹ and Youmans and Kampmeier.² Others—for example, Weinstein and Goodman,³ who reviewed the records of 509 patients with acute lobar pneumonia, of whom 37.5 per cent had syphilis—did not observe the favorable influence of antiluetic therapy on the course of unresolved pneumonia, as reported by Fitz-Hugh and Youmans and Kampmeier.

We believe that the case we are reporting here was very favorably influenced by antiluetic treatment.

Case Report

E. O., a 40-year-old white man, was admitted on October 20, 1938, to the Staten Island Hospital, complaining of diarrhea of four days' duration.

He stated that except for a "cold in his system" he was in good health until four days before admission, when he developed severe generalized abdominal cramps, followed by diarrhea and vomiting. Stools were yellowish-green, watery, and frequent. During the next three days, weakness and malaise increased, and a dry, short cough, which he had had for three or four months previously, became worse, with production of large amounts of thin, mucoid sputum.

His past history revealed that he had been susceptible to colds for "many years." X-rays of his chest were taken when he was 13 and again when he was 25, and were considered normal. He did not remember why the x-rays had been taken, but thought it was due to a cough he had at the time.

He had contracted syphilis at the age of 25, for which he "received a few injections." He had gonorrhea "two or three times" during his twenties—"easily cured." He was admitted to the hospital in 1936 and 1937 for treatment of a fistula-in-ano. His remaining past medical history is entirely irrelevant. His father died at 25 in the first World War and his mother at 53 of a "stroke."

On admission the temperature was 103.2 F. rectally; pulse rate, 130; respiratory rate, 24; and blood pressure, 120 systolic, and 60 diastolic.

Physical examination showed a poorly nourished and developed, tall, thin, prostrated white man, coughing at frequent intervals and somewhat dyspneic. He complained of pain in the right side of his chest.

The pupils were equal, regular, and reacted to light and accommodation. The tongue was heavily coated, the mouth dry, and the breath foul.

The essential physical pathologic changes were limited to the thorax and consisted of limitation of movement of the right chest; deviation of the trachea to the right; the presence of increased tactile fremitus, dullness, bronchial breathing, increased pectoriloquy, and a few scattered crepitant and small moist rales in the upper half of the right

chest posteriorly and in the right supraclavicular and infraclavicular regions anteriorly.

The apex point of maximal impulse was in the fifth intercostal space, 8 cm. to the left of the midsternal line. The heart sounds seemed normal.

The abdomen, except for slight distension, was normal. The liver, spleen, and kidneys were not palpable.

The admission diagnosis was chronic pulmonary tuberculosis with tuberculous pneumonia, intestinal tuberculosis, and latent syphilis.

On admission, the urine showed a specific gravity of 1.010, a 1 plus reaction for albumin, a few hyaline and granular casts, and a few pus cells. No red blood cells were seen. Hemoglobin was 73 per cent (Sahli); red blood count, 3,780,000; white blood count, 11,500, with 92 per cent neutrophils, 7 per cent lymphocytes, 1 per cent transitional cells, and 39 per cent band forms. Subsequent urinalyses were essentially normal. The hemoglobin ranged from 60 per cent to 66 per cent; the red blood count averaged 3,300,000; the white blood count, 11,500 to 15,260, with 70 per cent to 90 per cent neutrophils and 9 per cent band forms. A transfusion of 500 cc. of citrated blood was given on November 3 and again on November 21.

Sputum examinations for the tubercle bacillus were repeatedly negative. No pneumococci of types I to XXXII were found, but a few chains of streptococci were occasionally seen on smears. Blood cultures were all reported as negative. Stool examination for ova was negative. The Wassermann test was reported by the New York City Health Department as 4 plus.

An x-ray examination of the chest, made on October 28, was reported as showing "increase in density over the upper right lung field; retraction of the trachea to the right; indicative of consolidation, possibly with an old tuberculous lesion in the right apex. The cardiac shadow is markedly enlarged. Neoplasm to be investigated."

During the six days in the hospital, from October 20 to 25, his temperature ranged between 103 and 104 F. in the afternoons, and about to 99 to 100 F. in the mornings. The pulse was between 110 and 140 and the respirations between 24 and 48. The diarrhea disappeared on the fourth hospital day and the patient seemed improved.

Electrocardiographic studies on November 3, 22, and 25 showed paroxysmal auricular tachycardia with no deviation of the electrical axis.

On November 10, x-ray films of the chest showed that "some degree of resolution has taken place in the right lung, especially at the apex. The cardiac shadow appears smaller. The mediastinum is retracted to the affected side. Diagnosis: old fibrotic tuberculosis with superimposed pneumonia."

The patient continued acutely ill with productive cough, sweats, and right-sided chest pain. His fistula-in-ano was discharging freely and the dyspnea at night was difficult to manage.

For ten days after admission, from November 1 until November 10, he was given mercuric chloride, $\frac{1}{4}$ grain, and potassium iodide, 10 grains, three times a day, after meals. From November 10 until his discharge from the hospital on December 24 he was given 2 cc. of bismuth subsalicylate

Attending Physician and House Physician, respectively, of the Staten Island Hospital.

intramuscularly, twice the first week and once weekly thereafter.

From November 15 to 22 he received prontylin, getting 60 grains the first day, 45 grains the second day, and 30 grains daily for the next five days. No appreciable changes occurred except for a slight drop in the temperature.

X-ray films of the chest on November 18 showed no change over the previous report of November 10. The temperature in the second week, starting October 27, dropped to 101 F. and ranged between 97 and 101 F. until November 10, when it rose to a range of 100 to 102 F., with the pulse between 100 and 120 and respirations between 25 and 35. On November 24, the temperature dropped slightly, ranging between 99 and 101.4 F., with the pulse 110 to 120 and respiration 25 to 30. In the following week, the temperature, pulse, and respirations dropped, by slow lysis, until December 1, when they became normal and remained so until his discharge three weeks later.

During this time the patient's clinical condition improved slightly; his cough and chest pain persisted, however, and on November 25, he developed edema of the face and lower extremities. Digitalis therapy was instituted, with a rapid response, the edema completely subsiding in two days.

X-ray films of the chest on November 25 showed no change in the pulmonary picture over previous films taken, but x-rays taken December 8, revealed "marked resolution of the right upper lung field."

The patient had received, prior to this picture, five injections of bismuth over a period of four weeks, and for ten days before bismuth therapy was instituted he had received a total dosage of a $1\frac{1}{2}$ grain of mercuric chloride plus 300 grains of potassium iodide.

Despite a week of normal temperature and resolution as revealed by x-ray and physical examination, the patient's response was slow and unsatisfactory.

He continued to have severe chest pain, at times requiring morphine. On December 9, bronchoscopy was performed and it was reported that "the right upper lobe bronchus was dilated slightly and from its mouth was discharging whitish mucopurulent material containing several small, black, solid masses. These were aspirated."

Laboratory examination of this material showed no pus cells or organisms, however, and culture of the material grew only *Micrococcus tetragenus*.

Thereafter he improved rapidly. The cough disappeared, as did his chest pain, and he was discharged December 24, nine weeks after admission. X-ray on the day of discharge showed "lungs normal." The last week in the hospital on December 21, he received his first injection of neoarsphenamine intravenously, and since discharge he has been receiving intensive antiluetic therapy.

On the last visit, the patient stated that he feels fine, has gained considerable weight, has no cough, and works daily without fatigue.

Syphilis today is so often taken for granted that one is apt to neglect taking a specimen for a Wassermann test or to disregard the significance of a positive test in just such a case as the one we have reported.

In all cases of delayed resolution a Wassermann should be done, and if it is found to be positive, antiluetic treatment should be promptly instituted.

THE CONSERVATIVE MANAGEMENT OF OBSTETRIC PATIENTS PRESENTING PREMATURE RUPTURE OF THE FETAL MEMBRANES

BERNARD J. PISANI, M.D., New York City

IN READING the literature, one is confronted by conflicting reports about the effect of the premature rupture of the fetal membranes. Dry labor was always considered to be an unfavorable complication of pregnancy. The loss of the fluid wedge was believed to be the cause of dystocia and to have an undesirable effect upon both patient and infant. In more recent years, many obstetricians have felt that premature rupture of the fetal membranes is not so very great a hazard. Some claim that in many cases it may even shorten labor rather than prolong it. The object of this presentation is to discuss the results obtained in the conservative management of pregnant women entering the hospital with this complication.

Since 1934 a policy of definite conservatism has been pursued at Bellevue Hospital, and very satisfactory results have been obtained from the standpoint both of the mother and the fetus. In carrying out the management of such cases the following points are emphasized: A careful history and a thorough physical examination are performed. Once the history of rupture of the membranes has been obtained, no rectal or vaginal examinations are done, the patient not yet being in active labor. Careful palpation of the fetus for position and presentation is very important. A routine sterile preparation of the perineum is carried out, but no enemas are ordered. The patient is instructed at this time about the dangers of infection and is advised concerning touching of the genitalia, cleansing of the anal region after bowel evacuations, and warned against other possible sources of contamination. An inspection of the vulva is carried out to verify the presence of ruptured membranes. Freely flowing amniotic fluid with its characteristic odor, a shred of membranes, positive indicator tests, and the recovery of lanugo hair upon microscopic examination of the escaping fluid are all methods of assistance in making the positive diagnosis.

The woman is then kept at complete bed rest until the onset of labor. She is transferred to the ward where pulse and temperature recordings are made every four hours. If there is any suggestion of an abnormal position or presentation, of disproportion, or of any pelvic irregularity, the patient is subjected to x-ray study. The policy of careful waiting is carried out until

the woman spontaneously goes into labor. This method is in direct variance with that of many obstetricians who believe in active treatment of such a condition. Members of that school of thought may—and I quote—“... take no active steps until the membranes have been ruptured twenty-four hours. If at the end of that time labor has not begun, we administer castor oil and a soapsuds enema. Uterine contractions usually supervene. If they do not, we occasionally give small doses of pituitary extract. If labor has not begun following this treatment at the end of another day, we insert a Voorhees bag into the cervix.”¹

The reasons for this treatment were the fear of infection in the ruptured amniotic sac because of its proximity to a region harboring organisms—i.e., the cervix and vagina—and the difficulties attendant upon a dry labor. Because of these potential hazards, it was felt that the safest treatment consisted in the rapid emptying of the uterus. However, a safe method of emptying a uterus in the last trimester of pregnancy, especially in the presence of an unfavorable cervix, has not as yet been discovered. The cervix is often long and thick when early premature rupture of membranes occurs, and induction of labor is accompanied by inertia and dystocia. Radical treatment will frequently cause an infection of the amniotic sac. Constitutional reaction to this develops rapidly, and fetal death *in utero* is not uncommon.

Part of the rationale behind the conservative management lies in the avoidance of infection by abstaining from any active manipulation. In the absence of rectal or vaginal examinations, the flora of the vagina is not disturbed, and these organisms are not introduced mechanically into the cervical canal or into the amniotic cavity. In any rectal examination the smearing of the posterior vaginal wall over the cervical os must serve to introduce infection. On the other hand, escaping amniotic fluid probably acts as a cleansing cervical douche until the patient goes into labor. The perineal preparation and the instructions as to cleanliness that are given to the patient aid in decreasing the chances of contamination.

The early recognition of abnormalities by careful palpation and their further study by x-ray serve to prevent complications. Malpositions such as breech, transverse, and compound pres-

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1942.

intramuscularly, twice the first week and once weekly thereafter.

From November 15 to 22 he received prontosil, getting 60 grains the first day, 45 grains the second day, and 30 grains daily for the next five days. No appreciable changes occurred except for a slight drop in the temperature.

X-ray films of the chest on November 18 showed no change over the previous report of November 10. The temperature in the second week, starting October 27, dropped to 101 F. and ranged between 97 and 101 F. until November 10, when it rose to a range of 100 to 102 F., with the pulse between 100 and 120 and respirations between 25 and 35. On November 24, the temperature dropped slightly, ranging between 99 and 101.4 F., with the pulse 110 to 120 and respiration 25 to 30. In the following week, the temperature, pulse, and respirations dropped, by slow lysis, until December 1, when they became normal and remained so until his discharge three weeks later.

During this time the patient's clinical condition improved slightly; his cough and chest pain persisted, however, and on November 25, he developed edema of the face and lower extremities. Digitalis therapy was instituted, with a rapid response, the edema completely subsiding in two days.

X-ray films of the chest on November 25 showed no change in the pulmonary picture over previous films taken, but x-rays taken December 8, revealed "marked resolution of the right upper lung field."

The patient had received, prior to this picture, five injections of bismuth over a period of four weeks, and for ten days before bismuth therapy was instituted he had received a total dosage of a $1\frac{1}{2}$ grain of mercuric chloride plus 300 grains of potassium iodide.

Despite a week of normal temperature and resolution as revealed by x-ray and physical examination, the patient's response was slow and unsatisfactory.

He continued to have severe chest pain, at times requiring morphine. On December 9, bronchoscopy was performed and it was reported that "the right upper lobe bronchus was dilated slightly and from its mouth was discharging whitish mucopurulent material containing several small, black, solid masses. These were aspirated."

Laboratory examination of this material showed no pus cells or organisms, however, and culture of the material grew only *Micrococcus tetragenus*.

Thereafter he improved rapidly. The cough disappeared, as did his chest pain, and he was discharged December 24, nine weeks after admission. X-ray on the day of discharge showed "lungs normal." The last week in the hospital on December 21, he received his first injection of neoarsphenamine intravenously, and since discharge he has been receiving intensive antiluetic therapy.

On the last visit, the patient stated that he feels fine, has gained considerable weight, has no cough, and works daily without fatigue.

Syphilis today is so often taken for granted that one is apt to neglect taking a specimen for a Wassermann test or to disregard the significance of a positive test in just such a case as the one we have reported.

In all cases of delayed resolution a Wassermann should be done, and if it is found to be positive, antiluetic treatment should be promptly instituted.

TABLE 3.—MORBIDITY RATES—BELLEVUE HOSPITAL

Premature Series	All Obstetric Cases— 1940
100.0'—16 or 29.1%	17.2%
100.4'—10 or 20.8%	10.9%
101.0'—8 or 16.6%	6.4%

give rise to general septicemia or peritonitis. This plays a considerable part in the production of late fetal mortality.

We have attempted to segregate the cases of prolonged rupture of fetal membranes that have occurred at Bellevue Hospital since 1936. Only those patients known to have had ruptured membranes for a period longer than ninety-six hours, or four days, have been studied. It was found that premature rupture of the membranes occurred 48 times in 4,341 patients delivered. Many cases were found in which premature rupture occurred two or three days before the onset of labor, but this group was not analyzed. Of these 48 women 30 were multipara and 18 primipara. The time of gestation at which the rupture usually took place was within two weeks of the estimated date of confinement, averaging 8.3 months. In our series the duration of rupture membranes prior to the onset of labor averaged 7.7 days. It is interesting that 87 per cent of these patients were delivered normally; the rest were delivered by various operative procedures. The duration of labor for the entire group averaged 12.7 hours. However, the average duration of labor in the primipara was 12½ hours longer than that of the multiparous patient (21½ hours to 8 hours). The average hospital stay was 19.6 days.

Cause.—Many theories have been advanced to explain the cause of premature rupture of the membranes—large babies, hydramnios, twins, abnormal presentations, deformed pelvis, syphilis, and frequently trauma. Abnormal presentations were slightly more common in this series, but this may have been owing to accompanying complications such as contracted pelvis. In Table 1 the incidence of LOP positions is strikingly evident.

Deformities of the pelvis were present in several cases of our series. These varied from small gynecoid to true android types. There was no single predominant type of abnormal pelvis. Table 2 lists the principal complications that were found. A few others were present but are not included in this list because they occurred infrequently and probably have no relationship to the premature rupture of the membranes. It should also be noted that several patients had more than one complication.

Mortality.—In this series one maternal death occurred. This gives a maternal mortality of

TABLE 4.—TYPES OF DELIVERIES

Spontaneous vertex	40—87%
Forceps deliveries	4—8.7%
Low forceps—1	
Mid forceps—3	
Breech deliveries	2—4.3%

2.1 per cent. The death was a multipara transferred from the TBC service with far advanced tuberculosis. She delivered a premature baby (4 pounds 8 ounces) on April 8, 1939, developed phlebitis, and died on May 8, 1939, of pulmonary tuberculosis.

Five of the forty-six babies delivered died, thus making the fetal mortality 8.7 per cent. Of the total number of infants delivered 30 per cent were premature. Two were macerated stillbirths, while three were living, nonviable fetuses weighing less than 2 pounds, all of whom expired shortly after birth.

Morbidity.—Twelve of the morbid patients had normal spontaneous deliveries. The remaining 4 had forceps deliveries. Comparison of the series with the average morbidity rate of the Bellevue Obstetrical Service reveals a marked increase in all three standards, as seen in Table 3.

Type of Delivery.—Of the entire series, 87 per cent, or 40 cases, were delivered spontaneously; 8.7 per cent, or 4 cases, required forceps; and 4.35 per cent, or 2 cases, were breech (see Table 4).

Miscellaneous Notations.—Twelve patients in the series ran intermittent temperatures of 100 F. during their latent period in the hospital. Four of this group gave the history of vaginal examinations by their doctor prior to admission. Six of the group of 12 cases had a morbid course postpartum. A like number (6) had frank infection of the amniotic contents, with foul-smelling fluid escaping from the vagina. This developed during labor and is probably related to the alternate descent and ascent of the presenting part in the contaminated and dilating cervix.

A history of secondary rupture occurring at the time of delivery was obtained from doctors' notes on charts in 7 instances. A series of 8 episiotomies was done, 2 of these disrupting and requiring secondary repair. Such wound infection may well be related to infection of the amniotic sac. There were no cesarean sections.

For obstetric indications, and not because of the ruptured membranes, medical induction of labor was attempted in 7 cases with castor oil and quinine plus enema. Labor ensued in 3, but no effect occurred in the others. No pituitrin was employed in this group. The longest recorded labor was fifty-six hours, and the shortest was one hour in a multipara who had a nonviable infant. Antepartum medication in 7 cases was

entations, and cephalo-pelvic disproportion are, in many instances, accompanied by premature rupture of the membranes. Labor is usually protracted in these patients because of the abnormality which brought about the rupture of the membranes in the first place, and not, as many think, because of the premature loss of fluid. This fact is attested to by the low incidence of uterine inertia in large series of cases where for medical reasons labor has been successfully induced by artificial rupture of the membranes. Consequently, we may reasonably conclude that premature rupture is not necessarily the cause of protracted labor.

The diagnosis of primary rupture of the membranes, while usually easy, may sometimes be difficult to make. Occasionally there may be a slight rupture in both layers of the fetal membranes high up in the uterus, resulting in the escape of a small amount of fluid. In these cases the opening may heal spontaneously and the flow of fluid cease. There may also be a separation between the amnion and the chorion with an accumulation of fluid between the two layers, which may be followed by a rupture of the chorion and the escape of this fluid. Most often, however, primary rupture of the membranes is confused with the involuntary escape of urine resulting from pressure of the presenting part on the bladder or weakness of the urethral sphincter. Whenever the diagnosis is doubtful, the patient may be given methylene blue. A green stain in the fluid escaping is due to the dye excreted in the urine. A specimen of the fluid may be obtained with a wire loop and examined microscopically for lanugo hairs. Indicator tests based upon the presence of the alkaline reaction of amniotic fluid have been used. Pressure upward on the fetal pole will sometimes result in the escape of more fluid if the membranes have been ruptured. There is also the rare condition of hydrorrhea gravidarum, but we have no reported case of this type in our series.

Bed rest helps to prevent complications. Prolapse of the cord is less likely to occur; the loss of fluid will not be as great, thus preventing a truly dry uterus, and rest may aid in the healing of so-called "high leaks," if such a closure of the membranes is possible. Elevations of tempera-

ture are the first signs of sac invasion, and these should be carefully recorded. We have found that the woman with ruptured membranes should seek immediate hospitalization to avoid complications. The conservative method of treatment is also of value to the fetus and aids in reducing fetal mortality, because it prolongs the period of intrauterine life. One of our cases had ruptured membranes at the twenty-fifth week and carried on to thirty-four weeks, delivering a healthy premature infant weighing four pounds fourteen ounces. It is the thought of some pediatricians that fetal existence in a disturbed media may add to the powers of the premature child to survive.

Prior to considering our statistical findings, it is of value to mention the dangers of ruptured membranes, both maternal and fetal. In the case of the mother, spreading infection is most to be feared. An intrauterine infection of the amniotic sac when neglected may cause a myometritis, a severe parametritis, or more distant complications. Premature rupture of the membranes is often accompanied by premature labor, and the latter may be long in duration, depending upon the state of the cervix and the absence of a fluid wedge. Placental separation may occur. The absence of the hydrostatic bag may cause trauma to the cervix if the labor is strong and the expulsive forces powerful.

The dangers to the fetus are the incidence of prematurity, the loss of the protective cushion causing direct force upon the fetal skull, and an increase in the possibility of prolapse of the cord—frank or occult. The infection of the sac may have important effects on the fetus. Even when the mother escapes infection, it has long been known that in such cases the child, which is born alive, may succumb a few days later. Many have thought the baby may have become infected by swallowing the contaminated amniotic fluid. Direct growth of organisms takes place in the lungs in the presence of increased aspiration. Slemons and other workers have shown that in a certain proportion of cases the bacteria make their way through the amnion covering the fetal surface of the placenta, and, after invading the large vessels which lie just beneath it, gain access to the fetal circulation and

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the April 1 issue and will concern "Treatment of Some Common Diseases of the Eye"

Recent Advances in Sulfonamide Therapy

DR. DAVID P. BARR: We are to consider this morning the recent advances in sulfonamide therapy. The conference will be opened by Dr. Plummer.

DR. NORMAN PLUMMER: Since I reported to you a year ago at this conference on the status of sulfonamide therapy, there have been no outstanding discoveries in this field. However, there has been assembled much additional significant information. No really new sulfonamides have been described. No new theories on the sulfonamide action have been promulgated. No new uses of these drugs have been found, and no new toxic reactions have been reported. Nevertheless, those of us who are active in this field now feel very much more satisfied and secure in the use of these drugs. We have a clearer notion of the sulfonamide action. Even a year ago we were timid in almost every case that we treated, fearing some new reaction or development. In the beginning, when sulfapyridine first showed such miraculous recoveries in pneumonia, we were afraid that it was all a dream and that the results would not continue. Now, we are beyond that uncertainty, and we are developing accurate base lines for the uses and the untoward reactions of these drugs.

Although during the past year no distinctly new derivatives have been described, those preparations that already had been reported have been used in modified forms. Succinyl sulfathiazole, which has been given the trade name "sulfasuxidine," has been tried particularly in infections of the intestinal tract. This derivative of sulfathiazole is inert and in itself has no therapeutic value. However, it is broken down slowly to sulfathiazole in the intestinal tract and gives a method of depositing sulfathiazole in high concentration in the colon. Because sulfathiazole is only slightly absorbed from the colon, the blood and urine concentrations remain low as compared with those following the administration of sulfathiazole by the

usual methods, and consequently the danger of toxic reaction is much less. During the past year here and elsewhere, succinyl sulfathiazole has had a considerable trial in patients with colitis, both the chronic ulcerative and the acute forms, and it has been used both pre- and post-operatively, particularly in surgery on the large bowel. The high local concentration of sulfathiazole and the very low toxicity have been demonstrated clinically. Some investigators have been impressed by changes brought about in the intestinal flora. The clinical effect in chronic ulcerative colitis has not been impressive. The results in the acute diarrheas and in the surgical cases have not been fully appraised, and it is questionable whether they are any better than when the usual sulfathiazole or sulfadiazine is administered orally or the sodium salts are given parenterally.

In this country succinyl sulfathiazole—and the same may be said for sulfaguanidine—up to the present time has not given the results predicted on the basis of early experimental studies. However, these drugs may have great value in the war, particularly in desert countries where a chronic state of dehydration is almost universal. Under these conditions the usual sulfonamides, even in small dosage such as that recommended for prophylactic use, may be too dangerous. On the other hand, under such circumstances sulfaguanidine or succinyl sulfathiazole not only may be comparatively safe but, at the same time, highly effective.

Sulfadiazine, just as sulfathiazole, has been modified in various ways, with the hope that the resulting preparations would have new or greater actions. A slightly different drug has been created from sulfadiazine by linking an isomer of pyrimidine to the effective para-amino-benzene-sulfonamide group. This has been given the name of sulfapyrazine, and its clinical trial, particularly in pneumonia, now has been reported. The number of cases treated is not sufficient for final conclusions.

pantopon and scopolamine, while 2 were given sodium amytal. The remainder had no medication during labor.

Several suggestions present themselves after review of this series of cases. The incidence of low forceps cases seems very small when we consider that 30 per cent of the babies were premature. Possibly low forceps delivery might aid in the presence of resistant soft parts in lowering fetal mortality. The need of a positive and reliable test for the demonstration of ruptured membranes is obvious. The careful examination of the placenta and membranes after delivery may help in studying these complications. The custom of taking cultures, at the time of delivery, from the maternal vagina and cervix and the fetal oral and nasal cavities may aid in studying the morbidity of the mother and fetus. Proper use of uterine stimulants, castor oil, enemas, or pituitrin in minute doses after the onset of labor may aid in shortening the duration of labor as well as changing the type of labor, if obstetric complications such as disproportion or prematurity are ruled out before such adjuncts are employed.

Conclusions

1. Conservative management of the patient presenting premature rupture of fetal mem-

branes in the absence of labor is a safe procedure and its results warrant further study with the same method of treatment.

2. While fetal and maternal morbidity are greater than in the normal obstetric case, our results are better than those obtained with active methods of treatment in similar cases of ruptured membranes.

3. The danger of vaginal manipulation is apparent, in that 38 per cent of the morbid cases had at least one pelvic or rectal examination prior to entering the hospital.

4. The incidence of operative deliveries is much lower than with active methods of treatment.

5. Induction of labor was employed in only about 10 per cent of the cases, and for obstetric indications rather than because of the ruptured membranes.

6. More frequent use of low forceps in delivering the premature infant in the presence of resistant soft parts may reduce the fetal mortality.

7. Morbidity and mortality may be reduced by the free use of cultures to determine the type of invading organism and by the early administration of chemotherapy to fight infection.

REFRESHER COURSE AT ILLINOIS

A clinical course in laryngology, rhinology, and otology has been arranged by the University of Illinois College of Medicine for ear, nose, and throat specialists who are able to devote only a brief period to postgraduate study. The course will be given from March 22 to March 27.

Applicants should write to the Department of Oto-Laryngology, University of Illinois College of Medicine, 1853 West Polk Street, Chicago. In his letter the applicant must state his school, the date of his graduation, and details concerning his specialty training and experience. Registration is limited.

RHEUMATISM ASSOCIATION FOUNDED

The formal organization of the New York Rheumatism Association took place January 22 in New York City. The object of the new society will be to unite all local physicians who are interested in arthritis and rheumatic disorders in an attempt to improve the treatment of patients with arthritis, particularly those seen in arthritis clinics in Greater New York.

Officers elected at the first meeting include Dr. Russell L. Cecil, president; Dr. Martin H. Dawson, vice-president; and Dr. Edward F. Hartung, secretary-treasurer.

VOLUNTEER HEALTH ASSISTANTS NEEDED

An urgent request for 1,500 more women to enroll as Volunteer Health Assistants has been made by Health Commissioner Ernest L. Stebbins. All women between the ages of 20 and 45 may register for the work, which offers an opportunity to serve in a worth-while war effort and also to learn much about the field of public health nursing.

The Civilian Defense Volunteer Office is cooperating with Commissioner Stebbins in the drive for

volunteers, and registrations will be accepted at all neighborhood Civilian Defense Volunteer Offices.

The need is acute at present because so many trained volunteers must be ready to fill the vacancies left by public health nurses who are going into the armed services. A number of volunteers are already engaged in nontechnical work in child health stations, schools, and clinics.

sulfapyridine, then after sulfathiazole, and has been found to be the most frequent reaction following sulfadiazine. It may develop as early as the second day of therapy. Its occurrence is not definitely attributable to the size of the dosage or the level of the drug in the blood, to the fluid intake, to the reaction of the urine, or to a diminished renal function. Although each of these factors seems to exert some influence, there appears to be in addition some other factor unknown at the present time.

Shortly after renal symptoms were found to occur following the use of sulfapyridine, pathologic and experimental studies revealed that this drug and its acetyl derivative precipitated out in the urinary tract. In the case of sulfapyridine, this precipitation was thought to occur chiefly in the renal pelvis and ureters and to a lesser extent in the tubules. Following sulfathiazole and sulfadiazine, the renal reactions are not so common as after sulfapyridine. With all the more insoluble sulfonamides, however, there is a likelihood of involvement of the tubules and the glomeruli, and even some perivascular changes. At the present time there is little evidence that the sulfonamides, in the usual dosage, produce permanent injury to the kidneys. But this is one point that needs further study.

I should like to continue the discussion of this phase of the subject if there were time for it because I consider a knowledge of toxic reactions to be the basis of sulfonamide therapy.

Sulfadiazine has already been accepted by the Council of Pharmacy and Chemistry of the American Medical Association for the treatment of pneumococcal, Friedlander's bacillus, staphylococcal, gonococcal, hemolytic streptococcal, meningococcal, and urinary infections due to *Escherichia coli* and also aerobacter aerogenes.

In addition, there are a number of infections in which the sulfonamides have questionable value, and in these sulfadiazine seems to be as effective as the other sulfonamides.

There remains a formidable list of infections apparently not affected by the sulfonamides, and in these if a trial of sulfonamide therapy seems warranted, we think sulfadiazine may be used except in the infections of the intestinal tract in which there are indications for a trial of succinyl sulfathiazole or sulfaguanidine.

Chief among sulfonamide-resistant infections caused by bacteria are tuberculosis, diphtheria, typhoid and paratyphoid, and tularemia. Diseases caused by the Treponemata, fungi, and protozoan parasites are slightly, if at all, affected. Then there is the large group that we are so greatly concerned with today—the rickettsial and the virus infections. There is a question

whether any of these are benefited by the sulfonamides. It is true that encouraging results have been reported for trachoma and lymphogranuloma venereum, but even in these diseases there is doubt as to the effect on the initial virus infection. It may be only the secondary infections, so common in these conditions, that are altered.

I hope that when Dr. Cattell speaks he will tell us why the virus diseases as a group do not respond to the sulfonamides when many different bacteria are so positively affected.

There are many other developments in sulfonamide therapy that I should like to describe to you, such as our own and other studies on the control of the secondary infections following colds, and the excellent work being done on our surgical service and elsewhere in the treatment of burns and infected wounds with a variety of sulfonamide compounds, such as the sulfathiazole and sulfadiazine ointments; triethanolamine and sulfadiazine, which is applied as a spray; or the new "sulfa film" being used by Dr. Dingwall on our surgical service, which is applied either like adhesive tape or like vaseline gauze. However, our time is short, so I shall present just one other interesting phase of this subject.

That is the use of very high dosage of the sulfonamides in the treatment of some of the resistant conditions. All of our knowledge of high-dosage therapy, with high blood concentrations, has come since the introduction of sulfadiazine, principally because with sulfapyridine and sulfathiazole it was impossible to procure high levels because of their severe toxic reactions and poor absorption.

Shortly after we began to use sulfadiazine, we—and I should give Dr. Charles Wheeler credit for this—increased the dosage, and in a few cases maintained blood levels for several days between 25 and 50 mg. per cent. Fortunately none of these patients showed any severe reaction, but the responses were not particularly encouraging.

In a recent number of the *Journal of the American Medical Association*, Dr. George Dick of Chicago reported a case of subacute bacterial endocarditis in which at the start of therapy a single dose of 40 Gm. of sodium sulfadiazine was given intravenously. The blood level following this injection was 89 mg. per cent free and 90 mg. per cent total. Two hours later vomiting and abdominal cramps occurred. The urine output dropped to 215 cc. on the second day after the treatment, and it was seven days before it gradually returned to a normal amount. The blood urea nitrogen, which was normal at the start, rose in a week to 93.7

There is a strong indication that this closely related preparation will be almost the same as sulfadiazine. Apparently it has the same protective value and low toxicity. The reported protocols suggest that it is excreted slightly more slowly than sulfadiazine even though at the same time the blood levels seem to be somewhat lower.

Another sulfadiazine derivative that has been given clinical trial is sulfamethazine or sulfamethylthiazine. Shortly after the introduction of sulfadiazine, we were tempted to use this preparation. However, just at that time we and other persons were observing cases of serious peripheral neuropathy following the use of sulfamethylthiazole. Recently, in the English literature the use of this drug has been reported in a small number of pneumonia cases and also in a few patients with meningococcal meningitis and gonorrhea. It apparently has a good protective action and, because it is more soluble than sulfadiazine, the likelihood of renal damage is probably less. In this series a low incidence of toxic reactions is reported, and no cases of peripheral neuropathy or renal reaction are included.

Sulfadiazine now has had a very wide clinical usage, and it has maintained most of the advantages that originally were described for it. The uniform absorption, high blood concentration, and low acetylation have given it a decided superiority over sulfapyridine or sulfathiazole. While the incidence of toxic reactions after sulfadiazine is not so low as it was first thought to be, it is, nevertheless, lower than it is for any of the other sulfonamides, and probably for this reason more than any other this drug is becoming the sulfonamide of choice in almost every condition. Sulfapyridine is being used less and less. We find no indication for it except in an occasional case such as one of subacute bacterial endocarditis or pneumococcal meningitis, in which sulfadiazine has failed. However, I know of no such case in which a recovery occurred after sulfapyridine. Sulfanilamide, orally, also is being used infrequently. Even in cases of hemolytic streptococcal infection, sulfadiazine is more effective and more safely administered.

Sulfathiazole is still used commonly, but principally because of economy. It is more easily prepared and consequently the price is much lower than that of sulfadiazine, although now the difference is not nearly so great as it has been. Today the druggist is paying 80 cents for 100 sulfathiazole tablets and \$2.55 for sulfadiazine. In other words, at wholesale prices it would cost about 40 cents to treat a pneumonia patient with sulfathiazole and \$1.25

with sulfadiazine. Sulfathiazole has a slight experimental advantage over sulfadiazine. The in vitro studies show sulfathiazole to have a slightly stronger bacteriostatic action. According to these studies, the sulfonamides are now rated in the following order: sulfathiazole, sulfadiazine, sulfapyridine, sulfanilamide. The values depend upon concentration. It is true that after sulfadiazine administration, the blood and tissue levels are higher and more uniform than those of sulfathiazole, and this probably more than offsets the differences in bacteriostatic values.

I mentioned the fact that the low incidence of toxic reactions is the chief asset of sulfadiazine. Recently Dr. Wheeler and I assembled the sulfadiazine cases treated at the New York Hospital. We were interested particularly in the incidence of untoward reactions that followed the dosage recommended for the severe infections—namely, 2 or 4 Gm. initially, and then 1 Gm. every four hours.

TABLE.—TOXIC REACTIONS FOLLOWING SULFADIAZINE
912 Cases Having an Initial Dose of 2 or 4 Gm. and Then
1 Gm. Every Four Hours

Renal reaction alone	30
Renal reaction and drug fever	2
Renal reaction and drug rash	1
Drug rash alone	16
Drug rash and stomatitis	1
Drug rash and leukopenia	1
Drug fever alone	3
Nausea and vomiting	5
Changes in white blood cell count (leukopenia)	12
Agranulocytosis	0
Hemolytic anemia	0
Thrombocytopenia	1*
Stomatitis	1
Hepatitis	0
Conjunctivitis	1
Headache and vertigo	1
Total	75

* Fatal case.

From the above table on toxic reactions it should be emphasized that fatalities may result from the use of sulfadiazine, although if it is properly administered they occur very infrequently. The renal reaction is the most common and one of the most serious reactions. Nausea and vomiting and drug fever are very uncommon after sulfadiazine. In our series, almost 1,000 patients were treated with sulfadiazine, with no instance of hemolytic anemia or granulocytopenia, but this does not mean that these serious reactions never occur. It is most encouraging that 92 per cent of the patients can take the full dosage of sulfadiazine without any manifestation of toxicity.

The renal reactions as caused by sulfadiazine are manifested by abdominal or renal pain, gross or microscopic hematuria, oliguria or anuria, or nitrogen or sulfonamide retention in the blood. This type of reaction was observed first after

the same place in the enzyme system. However, the sulfonamides cannot serve the metabolic needs, and the substitution blocks the reaction and thus interferes with some essential cellular function. One of the difficulties with this theory is the relatively enormous quantity of sulfonamide necessary to neutralize the effects of the extremely small amount of para-amino-benzoic acid naturally present. Experimentally it has been shown that 1 part of the acid is equivalent to approximately 23,000 parts of the sulfonamides, denoting a corresponding difference in the affinity of these two substances in the reaction—a large but not impossible ratio of effectiveness.

Recently Harris and Kohn through a series of interesting experiments have brought strong support to the theory that the effect of the sulfonamides is due to interference with the synthesis of essential materials rather than to a direct action on the oxidation mechanisms. They tried the effects of all the commonly available amino acids and various other substances concerned in bacterial metabolism. Of these, other than *p*-amino-benzoic acid, only methionine inhibited the bacteriostatic action of the sulfonamides. This suggests that the action of sulfonamides is dependent upon the inhibition of an essential metabolic process involving methionine.

However, this is apparently not the whole story, since evidence has been accumulating which points to an influence of the sulfonamides on bacterial toxins. The most recent study is that of Hutner and Zahl in relation to the toxin of *Salmonella typhimurium*, which is fatal to mice. They observed that 20 mg. of sulfonamide given orally protect against many fatal doses of the toxin. This effect was largely neutralized by para-amino-benzoic acid, suggesting that sulfanilamide and para-amino-benzoic acid compete for the enzymes concerned in detoxification in a manner comparable to that described for bacteriostasis.

From a chemical standpoint sulfanilamide has a relatively simple structure—para-amino-benzene sulfonamide. Numerous synthetic modifications have been prepared by the chemist, and a large number of these are under investigation.

Since the recent discovery that the more complex azo dyes owe their activity to the liberation of sulfanilamide in the body, investigation has centered around this substance, and many derivatives have been prepared by the chemist. As a result we have accumulated a certain amount of information regarding the relationship of structure to activity in this group. It is a subject of great interest, but

here I can mention only a few of the more important factors:

1. The sulfonamide group ($-\text{SO}_2\text{NH}_2$) is inactive apart from the benzene ring to which it must be directly attached. However, the sulfonamide group is not essential, but rather the sulfur, which may be variously grouped, so long as it is linked to the benzene ring in the para position.

2. The amino group in the para position is important. If it is shifted to another position or another group is substituted there is a marked reduction in potency.

3. The addition of other groups to the sulfanilamide ring reduces potency.

4. Substitution in the sulfonamide group may modify the characteristics of the compound, but in many cases the antibacterial activity is retained or even enhanced.

All the commonly used compounds including sulfapyridine, sulfathiazole, sulfadiazine, and sulfaguanidine are of this character ($-\text{SO}_2\text{H.R.}$).

These various compounds differ among themselves both in regard to their physical and chemical characteristics and in their effectiveness as therapeutic agents. These properties determine both the choice of preparations and the details of administration. The more important considerations having a bearing on therapy are:

1. Effectiveness in relation to infecting organism (specificity).
2. Frequency and character of side actions.
3. Rate of absorption and elimination.
4. Solubility and pH of solutions.
5. Distribution in the body.
6. Rate and extent of acetylation.

Time does not permit the discussion of these very important aspects of the pharmacology of the sulfonamides. The differences between the various members of the group are quantitative rather than qualitative. However, their importance must be emphasized because they are the foundations upon which rational therapy must be built.

From a practical standpoint the question of toxicity is always a prime consideration. Various untoward symptoms are fairly commonly observed from all the sulfonamides. Unfortunately we know very little about the mechanism of these side actions, and we have no answer to the question of why under apparently similar conditions they occur in one patient and not in another. Experimental pharmacology has contributed very little. The lethal dose for these compounds in mice, dogs, and other animals, has, of course, been determined and their relative toxicity is known. But as I mentioned earlier, from a pharmacologic standpoint the sulfonamides are relatively inactive, and doses far in

ing, per cent and then gradually fell to normal. Ten days after the single dose, the blood sulfadiazine levels were 3.1 mg. per cent free, and 9 mg. per cent total. However, the temperature showed improvement and the blood culture was always sterile after the one treatment. When the patient's oliguria and nitrogen and sulfonamide retention had subsided, a short course of intravenous sodium sulfadiazine was given, during which the free sulfadiazine in the blood rose to 39.9 mg. per cent. This time there was no oliguria nor nitrogen retention. Dr. Dick reported this case six weeks after the massive dose was given, at which time there was no evidence of active endocarditis and none of permanent renal damage.

This case shows the great hazards of sulfadiazine in high dosage, for it was remarkable that the patient recovered from such a severe renal shut-down. On the other hand, it shows a remarkable therapeutic effect, and perhaps opens a new type of therapy.

The question that occurs to us who have followed a number of these cases is whether the high dosage was really necessary. It is our impression at the present time that from 5 to 10 per cent of the patients with subacute bacterial endocarditis show an arrest in the infectious process following the sulfonamides, but that it does not make a great deal of difference as to which of the sulfonamides is used, whether heparin is also given, or whether the drug is used in high dosage.

DR. BARR: Dr. Cattell will continue the discussion.

DR. McKEEN CATTELL: In reviewing the pharmacology of the sulfonamides I shall not cover the ground systematically, but shall confine my discussion to a few points of theoretic and practical interest.

The pharmacologist first of all wants to know how a drug acts. Through what mechanism are the observed effects brought about? In the case of the sulfonamides we are dealing with drugs which, in the mammalian organism, are almost inert, and thus differ from the general run of therapeutic agents. They have no specific action on any structure nor can they be characterized by any known influence on metabolic processes. However, when large doses are given to animals, toxic effects do, of course, occur, and these may be lethal. I shall return to this topic in a moment.

From a therapeutic standpoint, it is the action of the sulfonamides on the invading organism which is of prime interest. The usefulness of these substances as therapeutic agents is dependent upon their property of combating infections without injury to the host. Our

early views on sulfonamide action were dominated by those of the German and French investigators who did not regard the sulfonamides as antiseptics in the ordinary sense, but postulated that the action on bacteria was indirect and in some unspecified way required the cooperation of the body as a whole. This misconception doubtless had its origin in the fact that the prontosils were the first to be studied. These complex azo dyes are inactive *in vitro* but are reduced to sulfanilamide in the body. We now know that the sulfonamides exert a definite bacteriostatic action in concentrations corresponding to those occurring in the blood stream during therapy.

Thus our interest has shifted to the elucidation of the mechanism of action on the bacterial cell. Studies on the influence of these drugs on various aspects of metabolism are being actively pursued, any many theories have been advanced. These I cannot review at this time, but I should like to touch upon one recent development.

Three main hypotheses are current at the present time. The first of these is based upon data which are believed to indicate that oxidative changes are responsible for the conversion of the sulfonamide into more active compounds such as para-hydroxyl-amino-benzene sulfonamide, a compound which has been shown to be exceedingly active. The second assumes the formation of a derivative by mild oxidation which is a highly active anticatalase and the lethal action results from the accumulation of hydrogen peroxide. Both these hypotheses are based upon oxidations, but recently it has been shown in several laboratories that the bacteriostatic action of the sulfonamides is not necessarily reduced under anaerobic conditions. For this reason the third theory, based upon the hypothesis that the drug acts on bacteria to prevent them from utilizing the substrate, or upon the substrate to prevent it from being utilized by the bacteria, is attracting special attention.

It was discovered by Woods early in 1940 that *p*-amino-benzoic acid counteracts the bacteriostatic action of sulfanilamide, an influence which has since been shown to apply to all the sulfonamides. This observation is of great interest for several reasons: para-amino-benzoic acid is a constituent of the vitamin B complex and has been shown to be an essential substance for the normal growth of various forms, including chicks, molds, and bacteria. The English school (Woods, Fildes) postulates that *p*-amino-benzoic acid is an essential growth substance in those bacteria that are susceptible to the action of the sulfonamides. These two substances have a similar basic structure, and, according to the theory of Fildes, compete for

gens are conjugated, depending upon whether the dose is given by mouth or parenterally. If given by mouth, more is conjugated when it reaches the liver before being disseminated throughout the body.

INTERN: The sulfonamides have now been in use for a period of about five years. We have all seen many cases of jaundice and kidney damage. Have there been any later reports on such patients indicating permanent damage?

DR. BARR: Dr. Plummer, do you wish to comment on that?

DR. PLUMMER: Sulfadiazine, the drug with which our discussion is chiefly concerned, has been used for a much shorter period than that. Sulfadiazine was introduced in 1940 and we have been actually using it for just two years. The reactions that you refer to, particularly the jaundice, occurred much more often with sulfapyridine and probably more often with sulfapyridine and sulfathiazole than with sulfadiazine.

In the entire series presented in the table there was not even a suspected case of hepatitis and no case of jaundice.

Does your question relate to the development of reactions in patients who have received the sulfonamide a second time?

INTERN: What I should like to know is whether people who have not had the drug for many years have developed any disease of the kidney or liver that might be attributed to the initial dose of the drug.

DR. PLUMMER: On that particular point we do not have nearly so complete a follow-up as we would like. However, of the patients treated for pneumonia at Bellevue Hospital with sulfapyridine and then with sulfadiazine, a great number were followed in the clinic, and so far as I know no late reactions have been recognized, nor, so far as I know, elsewhere.

DR. HARRY GOLD: The City Health Department recommends sulfathiazole for the treatment of gonorrhea. I wonder why the choice of sulfathiazole.

DR. PLUMMER: Is that a recent recommendation?

DR. CATTELL: Yes.

DR. PLUMMER: I am not surprised because there has been a good deal of switching back and forth with these drugs. I believe that again it is the matter of economy of the sulfathiazole that has played a part. In many of these cases, particularly those in which a small dosage is used, there is not a great difference in the toxic reactions.

The gonococcus as a rule is susceptible to all of the sulfonamides, but the choice is between sulfathiazole and sulfadiazine.

I think that the final word has not been said, but on the basis of what we know now, particularly concerning the more uniform absorption, the better sulfadiazine levels, and the lower incidence of toxic reactions, sulfadiazine seems to be a slightly better drug.

DR. GOLD: May I, in relation to that point, ask one more question? I have seen somewhere the statement that there is a lesser tendency for the development of resistant strains of the gonococcus in relation to sulfathiazole than to some of the other sulfonamides. Do you have any information about this?

DR. PLUMMER: I know that a great deal of work is being done along that line but up to the present time we have no reason to believe that sulfathiazole would be less apt to produce drug resistance than would sulfanilamide, sulfapyridine, or sulfadiazine.

DR. CATTELL: There have been some recent reports, both laboratory and clinical, showing the development of tolerance by bacteria to one and not to another sulfonamide. A recent study of the problem in relation to gonorrhea was reported and the claim made that cases which became fast to certain other sulfonamides did not become fast to sulfathiazole to the same extent. However, this is certainly out of line with much other experimental evidence. Most studies on bacteria seem to show that when they are resistant to one sulfonamide the resistance applies to the whole group of drugs.

DR. PLUMMER: I think that Dr. McDermott, who has been working with us, has been going over the reports relating to that particular problem, and he might have something to add.

DR. W. McDERMOTT: There is a large body of evidence indicating that all the sulfonamides act in about the same way. There is not one drug which is better with respect to the streptococci or the staphylococci. The difference is quantitative only. Sulfadiazine is a stronger sulfonamide than sulfapyridine or sulfanilamide, but there are no tricks that one has that the other does not have. So I doubt whether the resistant organism could be made non-resistant by using another drug.

DR. GOLD: In regard to organism specificity of the sulfonamides, the study of Wyss, Grabau, and Schmelkes is of interest. By means of a special technic making use of the antagonism between the sulfonamides and para-aminobenzoic acid, they obtained evidence that a wide variety of organisms showed equal sensitiveness to different sulfonamides.

DR. PLUMMER: Dr. McDermott, would you also make a point about the effect of pH? That is a factor to be considered.

excess of the therapeutic range are required for the production of toxic symptoms in animals. With the exception of damage to kidney function, the side actions which are occasionally so serious in man have not been reproduced in animals. Animals, on the other hand, under the large doses necessary, present a picture of poisoning bearing no relation to the side actions ordinarily seen in man.

Because it is rather the exceptional case that develops one of the more serious toxic symptoms during therapy, there is an unfortunate tendency to conclude that the patient possessed an idiosyncrasy to the drug—whatever that means. This is merely hiding behind the cloak of ignorance. I believe that the accumulated evidence justifies the conclusion that the sulfonamides have a definite pharmacologic action on a number of the systems of the body, the more important being depression of the bone marrow, damage to the kidneys and the liver, and a more generalized metabolic action which is reflected in the skin rash and "drug fever." Is it not probable that only in certain cases, depending upon individual variation and pathology, does the action proceed to an extent that can be recognized through the occurrence of symptomatology? The development of more precise functional tests should provide the means of detecting and following these early changes, which at the present time are too often recognized only after irreversible damage has been done.

For successful therapy the concentration of the sulfonamide in the blood must be maintained at an effective level, usually between 5 and 10 mg. per cent. The relationship between blood concentration and the occurrence of toxic symptoms has not been so clear. Many cases have been reported in which serious toxic manifestations have developed at low sulfonamide levels. In fact, the statement is frequently made in the clinical literature that larger doses of the sulfonamides are no more likely to cause difficulty than the smaller ones. This comes as a serious blow to the pharmacologist, who will need to abandon the quantitative aspects of his science if the dosage-response relationship cannot be sustained. Precise information is difficult to obtain, but I have confidence that after the smoke clears it will be found that the toxic effects of the sulfonamides are related to the amount of drug administered.

Finally I should like to touch upon the interesting problem of so-called "drug fastness" as it relates to the sulfonamides. There is a growing body of evidence, partly clinical and partly experimental, indicating that under certain circumstances these drugs may lose

their effectiveness in the course of time. The most complete evidence has been obtained for the pneumococcus, in which form, and in several laboratories, it has been shown both in vitro and in vivo that treatment with sublethal doses over a long period of time results in a drug-resistant strain. A recent report on the subject will be found in a paper by Schmidt, Sesler, and Dettwiler, of Cincinnati. Several strains of the pneumococcus were made highly resistant to sulfapyridine by serial passage through mice treated with less than curative doses. In the course of time strains were developed which multiplied rapidly in the highest concentrations of sulfapyridine that can be maintained in the body fluids or in artificial media, and they were resistant to other sulfonamides as well. This suggests the survival of the fittest—i.e., the selective propagation of the drug-resistant variants. The practical implications of these findings have been emphasized by the authors. Since resistance is known to develop during clinical use, it is conceivable that the dissemination of those organisms by carriers will ultimately curtail the value of sulfonamide therapy.

I have touched on only a few of the many pharmacologic topics of interest in connection with the sulfonamides. Perhaps we can pursue the subject further in discussion.

DR. C. H. WHEELER: With reference to the table of toxic reactions, I think many of you who have been working here will be surprised to see some of those values so low. We should emphasize what Dr. Plummer did not have time to emphasize—that this list includes no patients who received even a single injection of sodium sulfadiazine intravenously. It includes no patients who had been treated for even a day with sulfathiazole or one of the other drugs before they received sulfadiazine. Only patients who had received the standard oral dose of sulfadiazine and had never received any other sulfonamide in the immediate past are included.

DR. EPHRAIM SHORR: In the case of sulfadiazine parenterally, were not the blood values excessive even though the dose was not large?

DR. PLUMMER: No, they were not unusually high.

DR. WHEELER: For instance, we have had a severe renal reaction after a single initial dose of sulfadiazine intravenously.

DR. SHORR: That brings up a point with respect to changes in the molecule which we speak of as detoxification changes. I understand that acetylation in the liver represents the major change. This is a principle that not only holds for sulfadiazine but also for some of the synthetic estrogens. There is a great difference in the speed with which synthetic estro-

results from an interference with the utilization of para-amino-benzoic acid, an essential constituent for bacterial growth. Methionine and certain other growth-promoting substances have also been shown to interfere with the bacteriostatic action of the sulfonamides. Furthermore, the mechanism apparently involves also bacterial toxins, since the sulfonamides have been found to protect mice against fatal doses

of Salmonella toxin, an effect which is neutralized by para-amino-benzoic acid. Another interesting aspect of the action of sulfonamides is the development of drug-resistant strains when the organisms are constantly exposed to sublethal concentrations of the drug. This occurs both in vivo and in vitro, and has obvious importance from the standpoint of the possible dissemination of drug-resistant strains by carriers.

NATIONAL HEALTH ADVISORY COUNCIL

A National Health Advisory Council was organized in Washington on February 5 to project and carry out a broad program looking to health conservation as one of the most important factors in winning the war.

The Council was created by the Chamber of Commerce of the United States to consider national health problems in relation to the war program.

The meeting was opened with a statement by National Chamber President Eric A. Johnston, which said in part:

"... aside from the direct benefits accruing to the war effort from health conservation, we must consider the staggering cost of disease. Together with physical disability, it is taxing the American people \$10,000,000,000 a year. This tax everyone pays and no one gets. It is a 5 to 10 per cent drag on war operations."

General chairman of the Council is Dr. James S. McLester, professor of medicine at the University of Alabama, who outlined the contemplated nationwide program. He said:

"The plan is for a broad educational effort designed to raise the nation's health levels. Once established, it is earnestly hoped that these levels can be maintained after the war is won, as a means of continuing improvement of the national welfare."

The National Health Advisory Council will serve to channel approved technical health information developed by the country's many scientific associations to business organizations and their members throughout the country, so there may be brought about a better public understanding and appreciation of medical science as a means of safeguarding public health to win the war. It will work through the Chamber of Commerce of the United States as a central organization, which, in turn, will work through its far-flung membership of trade associations, chambers of commerce, and corporations and firms. The Council's membership starts with thirty of the nation's leading medical and health authorities. This membership will be increased as the work progresses.

The council's first meeting, presided over by James L. Madden, of New York, vice-president of the Metropolitan Life Insurance Company, and chairman of the National Chamber's Insurance Department Committee, heard a round-table discussion of wartime health problems. Discussion leaders were Dr. James S. McLester, professor of medicine, University of Alabama; Dr. Wilson G. Smillie, Medical School, Cornell University, New York City; Dr. Felix J. Underwood, state health officer, Jackson, Mississippi; Dr. Leverett D. Bristol, health director, American Telephone & Telegraph Company, New York City; and Dr. H. M. Marvin, Yale University, New Haven, Connecticut.

At a luncheon meeting Dr. Thomas Parran, Sur-

geon General of the United States, talked on the health state of the Nation.

The Committees of the Health Advisory Council are:

General Chairman—Dr. James S. McLester, professor of medicine, University of Alabama.

Community—Chairman, Dr. Wilson G. Smillie, Medical School, Cornell University; Dr. Paul White, president, American Heart Association, Massachusetts General Hospital; Dr. J. Burns Amberson, Bellevue Hospital; Dr. George Kosmak, professor of obstetrics, New York Academy of Medicine; Dr. George R. Cowgill, Yale University; Dr. Harry Bakwin, professor of pediatrics, New York University College of Medicine; Dr. Ernest L. Stebbins, Commissioner of Health, New York City; Dr. F. J. Underwood, State Health Officer, Jackson, Mississippi; Mr. Bailey Burritt, president, Committee on Neighborhood Health Development, New York City; Dr. Henry F. Vaughan, University of Michigan.

Industrial—Chairman, Dr. Leverett D. Bristol, Health Director, American Telephone & Telegraph Company, New York City; Dr. Harvey Bartle, Pennsylvania Railroad, Philadelphia; Professor Philip Drinker, Ph.D., Harvard University, School of Public Health; Dr. Anthony Lanza, chief, Occupational Hygiene Section, Office of Surgeon General, U.S. Army, Washington, D.C.; Dr. John J. Prendergast, medical director, Chrysler Corporation, Detroit, Michigan; Dr. Loyal A. Shoudy, Bethlehem Steel Corporation, Bethlehem, Pennsylvania; Dr. W. A. Sawyer, medical director, Eastman Kodak Company, Rochester, New York; Dr. Harry E. Ungerleider, assistant medical director, Equitable Life Assurance Society, New York City; Dr. John J. Wittmer, Consolidated Edison Company, New York City; Mr. John Dewey Dorsett, manager, Casualty Department, Association of Casualty & Surety Executives, New York City; Mr. G. W. Hardy, Lumbermen's Mutual Casualty Company, Chicago, Illinois.

Individual—Chairman, Dr. James E. Paullin, professor of medicine, Emory University, Atlanta, Georgia; Dr. Leroy Gardner, member board of directors, National Tuberculosis Association; Dr. George Morris Piersol, professor of medicine, University of Pennsylvania; Dr. Russell Wilder, Mayo Clinic; Dr. Alfred Blalock, professor of surgery, Johns Hopkins Hospital; Dr. Joseph C. Doane, York & Tabor Road, Philadelphia, Pennsylvania; Miss Marion G. Howell, R.N., president, National Organization for Public Health Nursing, New York City; Dr. Arthur F. Chace, president, New York Academy of Medicine; Dr. H. M. Marvin, Yale University; Dr. Louis Hamman, Baltimore, Maryland; Dr. Wallace C. Yater, professor of medicine, Georgetown University, Washington, D.C.

DR. McDERMOTT: Drs. Fox, Schmelkes, and Wyss, and a number of other people who have been working on the problem, have shown that the chemical and physical environment that the drug is going to work in is a factor. The same effect, for example, may be produced with sulfanilamide in a pH of 10 as with sulfathiazole in a pH of 7 or 7.4.

I think that evidence is conclusive that there is no qualitative difference among the drugs but that it is purely quantitative.

DR. WALTER MODELL: I wanted to ask a question about a recent paper which concluded that amino-acetic acid and ascorbic acid detoxify the sulfonamides but do not reduce their therapeutic efficacy. Do you know the paper?

DR. PLUMMER: I remember the paper, and there have been two or three similar reports in which some substance has been said to do that, but I think that no conclusive evidence has been presented. The evidence is highly theoretic and certainly there is no definite clinical or statistical proof.

DR. SHORR: It is curious that the acid-fast group, which is so resistant to sulfonamide, can be grown very well in a synthetic medium which contains no benzene ring in any of its constituents, so it would appear that para-amino-benzoic acid may be either synthesized by the organism or that it is not necessary for growth.

STUDENT: Is the sodium sulfadiazine preparation stable?

DR. PLUMMER: Sodium sulfadiazine solution, if kept under certain conditions, is stable. We have used a preparation of 25 per cent sodium sulfadiazine contained in ampules that the Lederle Laboratories, Inc., made for us, and we have found no reason to believe that after several months it had lost its potency or changed in any way.

STUDENT: Is there any correlation between pH of the urine and the incidence of renal reactions in the sulfadiazine therapy?

DR. WHEELER: It has been shown quite clearly in vitro that the solubility of sulfadiazine is much greater as the alkalinity of the solution is increased, and there is some clinical evidence that alkalization of the urine by the use of sodium bicarbonate increases the solubility of the drug and decreases the likelihood of renal reactions.

I think at the moment that most people would agree that patients receiving the full dosage of these drugs should be given sodium bicarbonate because, if carefully supervised, it will do them no harm and it may have some effect in preventing the renal reactions.

DR. SHORR: How much urinary output would you suggest?

DR. WHEELER: In general I think it is ideal to have an output of around 1,000 cc. a day when that is feasible. On the other hand, we have had many patients who had severe renal toxic effects even though their output had never been less than 1,000 cc., and we had quite a few who had toxic effects with a renal output of 2,000 or 3,000 cc. So it is certainly true that a large output does not guarantee that no reaction will occur.

Summary

DR. CATTELL: There have been no outstanding new discoveries in the field of sulfonamide therapy since our conference of a year ago, but on the other hand the period has been one of continual progress in the applications of the sulfonamides. Succinyl sulfathiazole has provided us with a method of securing high concentrations of sulfathiazole in the gastrointestinal tract, and its relative safety gives it a secure position in the therapy of various infections of the tract. Further experience with sulfapyrazine suggests that it does not differ significantly from that of its isomer, sulfadiazine. Sulfamethyldiazine has been used in England and, because of its relatively high solubility and in a very limited experience a low incidence of toxic reactions, is deserving of further study. A fairly extensive experience with sulfadiazine has borne out the earlier impression that the incidence of toxic reactions from it is very low. In a series of 912 cases treated with sulfadiazine at the New York Hospital, 92 per cent took the full dosage of sulfadiazine with no manifestation of toxicity. Renal reaction due to precipitation in the urinary tract is now recognized as one of the most frequent and serious complications of the use of sulfadiazine. Fortunately, with proper supervision these cases can be recognized early, and in the present series no fatalities occurred from this cause. The only fatal case was in a patient who developed thrombocytopenia.

Sulfadiazine is second only to sulfathiazole in its bacteriostatic action and the slight difference is probably offset by the fact that after sulfadiazine the blood and tissue levels are higher and more uniform than is the case with sulfathiazole. Sulfadiazine now has a wide range of clinical usage and appears to be effective in all cases in which the sulfonamides are of value.

During the past year numerous studies have been reported with a view to elucidating the mechanism of action of the sulfonamides on bacteria. In general, this has tended to confirm the prevailing view that bacteriostasis

entire population and so indirectly to the practicing physician. It sees in these plans a great opportunity for modern public health education. We aim to be modern in the use of our professional ability. We must not fail to recognize that we

must also be modern in making our professional resources available.*

*Later issues of the JOURNAL will carry an outline of practical systems for prepayment Medical Care Insurance.

PUBLIC EDUCATION PROGRAM ON CANCER STILL IS INADEQUATE

The public education program on the cancer problem is still inadequate and ineffective, Drs. Charles R. Harms, Jules A. Plaut, and Ashley W. Oughterson of New Haven, Connecticut, declare in *J.A.M.A.* in a report of their study of the causes of delay in treatment of cancer in 155 patients.

It was found that only about one-fourth of the patients had read about cancer and that all but 2 of these had obtained their information from newspapers and popular magazines. Only 2 admitted reading public health pamphlets. . . .

"Delay in the diagnosis and treatment of cancer," the three physicians say, "is one of the most important factors in the failure to obtain better results by the methods of treatment now available. . . ."

They interviewed 158 successive cancer patients as they were admitted to the New Haven Hospital or Tumor Clinic. Three patients came immediately to the hospital for emergency treatment, 1 because of intestinal obstruction and 2 because of hemorrhage.

"The definition of delay due either to the patient or to the physician," they explain, "must necessarily be arbitrary. . . ."

Eliminating the 3 patients who reported immediately for treatment, the authors say that 85 patients, or 54.8 per cent, were responsible for the delay, while 27 physicians, or 17.4 per cent, were said to be responsible. Both the patient and the physician were responsible for the delay in 43 instances, or 27.8 per cent.

"The patient was found to be either wholly or in part responsible for the delay in 128 instances, or 82.6 per cent," the three physicians found. "All but 7 of the 128 patient delays (121, or 94.5 per cent) were initial delays. The other 7 did not follow the physician's advice in spite of his efforts. . . ."

The causes for delay among the 153 patients were reported to be as follows: symptoms "not serious enough," 56.9 per cent; negligence, 11.3 per cent; no delay on the part of the patient, 11.3 per cent; expense, 10.1 per cent; ignorance, 6.9 per cent; fear

of cancer, 1.4 per cent; fear of doctors, 1.4 per cent; . . . 7 per cent.

As the authors say that "failure to recognize signs and symptoms accounts for most of the delay. This is primarily an educational problem which is obviously not being met by present methods. The second most important factor defined as negligence may also in large part be corrected by proper education. The economic factor accounts for 10 per cent of the group. . . ."

"The effectiveness of an education problem can best be judged by the content of knowledge possessed by the group as well as its effectiveness in producing appropriate action. The following general questions were asked in order to evaluate the information regarding cancer possessed by the group: How many patients with malignant tumors think of cancer as the cause of their complaints? Only 21, or 13 per cent, answered in the affirmative. Breast cancer was responsible for 13 of these. The median delay for patients who thought they had breast cancer was 3.25 months, while the median delay for all breast cancer was 6.5 months. This suggests that the delay could be halved if all patients were aware of the significance of their symptoms. It was also found that only 42, or 26 per cent, of the patients had read about cancer. . . . Only 2, or 1.2 per cent, had ever heard a lecture on cancer, and both of these had been while attending National Hospital Day. Although the entire group seemed poorly informed regarding cancer, 80 per cent thought that cancer was curable and 91 per cent thought that treatment was urgent. . . ."

As for the delay by the physician in making a diagnosis, the authors point out that this is important but explain that "the information on which these data are based was obtained chiefly from the patient, and it is likely that many of these patients did not cooperate by returning to their physicians for further study. For accurate information it would be necessary to interview both the patient and physician. . . ."

BETHUNE SCHOLARSHIPS AWARDED AGAIN

The Bethune medical scholarships, established in 1941 in memory of Dr. Norman Bethune, a Canadian physician who was one of the organizers of medical service for China's northwest guerrilla region, are

being offered again this year, the China Aid Council announces. The scholarships are to be awarded yearly to two students who distinguish themselves in the medical field.

Special Article

VOLUNTARY PREPAYMENT FOR MEDICAL CARE

HERBERT H. BAUCKUS, M.D., Buffalo

Chairman, Council Committee on Public Relations and Economics

Medical Society of the State of New York

ALWAYS in our dreams we hear the turn of the key that shall open every access of ideal medical care to all mankind. There is a human limit to the forward theme of our professional responsibility to comfort and preserve, although research and the good old-fashioned method of rowing hard against the stream of life will keep our incomparable American medicine ever modern and will make it better. But, no less, we owe it to those we serve that the accumulated skill and knowledge we possess today be made available for use by all of our people.

To teach both the well and the sick to accept great advantage of preventive and curative medicine regularly and promptly is a difficult task.

Voluntary prepayment for medical care, with nonprofit insurance to provide the means for distributing the costs of family illness over larger groups, is a system that embodies in its economic protective functions equally important health- and character-building features. It teaches health and health responsibility to the individual and to the family. The mutual character of the plan in itself makes for prevention of disease. He who would protect his welfare must accept a personal part in his community health program.

Such voluntary plans are still in the early stages of practical development, but they are beyond the period of uncertain experimentation. They are especially designed to appeal to regularly employed workers. Voluntarily, the worker agrees to set aside a small portion of his monthly earnings to create the funds disbursed by the insurance corporation to pay for the expenses of medical care. Since these plans are for mutual benefit, have mutual management, are nonprofit, cost comparatively little for administration, and are flexible to the needs of the participating groups, it would appear that the only reason they are slow to sell is that they are not understood. The choice of the physician is left to the patient. The modern method of administering medical services is not at all changed. The cost of these services is not increased, and in many instances it is reduced. The payment received by the practicing physician

under the present medical indemnity type of insurance is the usual fee regularly associated with modern high standards of medical practice. There is no trend to inferior or indifferent service. Subscriber-patients to such professionally approved plans have found their investment a most desirable one, and withdrawals seldom occur. They are learning that it pays to call for medical service when it is first needed. And in so learning, they have absorbed one of the most important lessons of good public health.

The practicing physicians working under a prepayment medical plan should consider:

1. That neither in war, nor in peace can we afford to leave people without medical care. Industrial producers of war materials, and their families, must be kept in good health.
2. That the average American prefers and is willing to pay for his medical care.
3. That if he is helped to budget for himself and his family, he will learn to attend to illness at an early stage, thereby protecting much needed civilian health, as well as conserving the doctor's time.
4. That if he is taught to budget regularly and within his income, he will continue to consider medical care a basic necessity next to shelter, food, and clothing, even in times of smaller earnings.
5. That the physician's leadership in promoting such plans is needed.
6. That physicians should discuss the possibility of a prepayment medical plan for their counties with community representatives including:

- (a) Social agencies
- (b) Industrial representatives
- (c) Labor leaders
- (d) Representatives from community and dominant nationality groups

The Medical Society of the State of New York is committed to the full approval of voluntary nonprofit Medical Expense Indemnity Insurance. It urges its members to participate in this movement wherever possible to advance the progress of good health in this country. It feels that such plans are greatly to the benefit of the

But just as the merchant ship must meet certain specifications to be converted to war purposes, so must the civilian meet certain specifications—both physical and mental. It is the mental requirements which are of interest here. Approximately the same standards are used for peacetime as for wartime service. The differences in selection which result are due to the speed necessary in war, and to the attitude of the average volunteer as compared with the average selectee. The speed of induction of the wartime recruit is likely to increase the number of mental misfits in the services. The average volunteer (whether in peace or war) is apt to disguise any defects: forget that his mother is insane, or that he has had delirium tremens or fits. The selectee, on the contrary, is more likely to remember everything which might prevent his induction, even remember things that never existed. Therefore each class presents its distinctive problem.

Certainly the man whose mental buoyancy corresponds to the leaky hulk will not make a good sailor, soldier, or marine. The unsocial, the moron, the hysterical, and the psychotic must be excluded. The alert noncommissioned officer on recruiting duty knows this. So does the recruiting officer, line or medical, and they can accomplish a great deal in rejecting men whose minds lack stability or buoyancy.

Weeding Out the Unseaworthy

Available to selection boards and training stations are psychiatrists. And a good psychiatrist may decrease the number of unseaworthy minds admitted to the services. These specialists in mental diseases have emphasized the fact that 60 per cent of the veterans of World War I who required hospitalization for disease were sick with neuropsychiatric diseases. (Each cost the taxpayers \$30,000.) But they have overemphasized the inference that even with all the time they want (and they need a lot of time) they can greatly reduce that percentage in this war by selection alone. And unless the psychiatrist is both a good psychiatrist and has a clear idea of the service for which he is selecting men, he might pull out a lot of valuable military seedlings along with his weeds. There is a type of man who is a poor, not to say bad citizen, who in peacetime services is frequently in trouble, but who in war makes the ideal fighting man. I recall a marine of the Second Division in France in 1918. "Me and the major is the only ones what rates a orderly," he used to say, because he was always under guard for some breach of discipline. But at Bois de Belleau in June and again at the counteroffensive from Villers Cotterets in July he fought like a demon. Every experienced

military man has seen such characters. "Admiral X," remarked a ranking officer recently, "has just enough of the so-and-so in him to make a good leader." If this war is to be won, in the writer's opinion men of this type must not be excluded even at the risk of wasting time and money on a few incorrigibles.

The ideal of the psychiatrist is to reconstruct a picture of a recruit's mental background and obtain an accurate evaluation of his present mental stability. That is all. But even if a man's background is perfect (it never is), and his present mental stability is unquestionable, that does not prove his mind can withstand the particular shock to which this war is destined to subject him. The best psychiatrist and medical officer combined cannot foresee the personal role the man is to play in this particular war.*

The best that can be done, therefore, is to pick men with reasonably substantial minds just as the Navy picks for war conversion ships which are reasonably substantial. A great deal of thought has been put on the selection of men to withstand the mental shock of war. But too little emphasis has been put on a mental preparation during conversion to increase resistance to that shock; and hardly any emphasis has been put upon mental supervision—damage control—to maintain resistance to shock. As I write, a fourth of the nonbattle disabilities in the active Navy are due to mental conditions. And these are permanent disabilities. It is high time that the subjects of mental conversion to war purposes and the damage control of the mind be given the thought they deserve.

First Day the Hard Way

The civilian who has been selected as physically and mentally fit for the Navy is immunized against typhoid, tetanus, and yellow fever; he is taught to shoot and his muscles are developed. Also immediately he receives his first mental shock—his transfer from the comparative freedom of a domestic environment to the intimacy of a restricted community with definitely marked distinctions of rank and privileges.

It is significant that of those in the first World War who finally foundered mentally, almost one-tenth went under on the *first day* of military service. It would not be surprising if the same occurs in this war, judging by this story of a

* Although Captain Michael writes as an experienced medical officer, it should be pointed out in fairness to the psychiatrists that these specialists in mental diseases actually have no authority to pull selectees from military service. They make their diagnoses; the decisions are made by others. Thus Dr. George S. Stevenson, medical director of the National Committee for Mental Hygiene, states that the tendency has been for too many clear cases of neurosis, even psychosis, to get into the Army—rather than for borderline cases to be ruled out.—THE EDITORS OF SURVEY GRAPHIC

Special Article

MEN'S MINDS AND SHIPS

W. H. MICHAEL, Captain (Medical Corps), U.S. Navy*

WE SAW a holocaust of men and ships at Pearl Harbor. In all the horror of that morning it seemed that man had done his worst in the destruction of man and the works of man.

But beginning that day and on through the days that followed, it became evident that the damage had gone beyond visible destruction. It had wrought invisible havoc with men's minds as well as with men's bodies and men's ships.

Among the wounded was a big healthy-looking sailor. He was trembling, his face anxious, his eyes wild. "Where's your wound?" a medical officer asked. "I'm not wounded. I try, but I just can't take it." And he went on sadly repeating, "I can't take it."

"Shell shock. Anxiety neurosis," murmured the Navy surgeon.

On the next day, and the next, and the next, more cases of anxiety neurosis appeared. It is the commonest acute form of the violent mental shock of war (not to be confused with the physical shock of explosive blasts causing breaks in tissue with visceral rupture or multiple hemorrhages within the skull, the chest, or the abdomen). But there were other varieties of damage to the mind: soldiers' heart (effort syndrome), gastric neuroses, dementia praecox, and many forms of psychosis all precipitated by the shock of war. For the unconscious mind finds devious ways to defend the body, and the mind whose balance has been destroyed devises devious means of creating a fanciful, a more pleasant mental environment to replace a real material environment which has become intolerable.

The same action that had destroyed the balance and buoyancy of ships had also destroyed the same elements in men's minds. For men's minds are like ships. Both go down when their buoyancy is destroyed. Some minds are leaky tramps and make heavy weather, even founder in the tranquility of peace. Some are destroyers—quick, aggressive, but not able to withstand a great shock, a torpedo; and some minds are like battleships which may withstand the shock of one or two torpedoes and remain afloat. *But no ship, no mind is unsinkable.*

* The views and opinions expressed in this article are not necessarily those of the Navy Department.

Even Trained Men Are Like Converted Merchant Ships

Yet there is an essential difference between ships and minds: When a sailor—who knew his Hawaiian—saw the destroyer *Shaw* explode in the drydock, he exclaimed: "That tin can is *pau*." Yet in two months the *Shaw* went back to the mainland under her own steam. I saw her picture recently. She has a new bow, is ready to fight.

But the mental, the invisible casualties: as far as active participation in the war is concerned, they are *pau*. They are out of active service for good. Of all the nonbattle casualties who went to the mainland in the month after the attack, approximately half were sick with mental disease. The best they can hope for is an apparent recovery and a quiet job. Ships can be rebuilt, better, more modern than before; minds can only be patched.

When a ship goes down, the cause of sinking is easily discoverable. The ship's sides may have been blown in, watertight bulkheads may have given way. But sometimes ships sink from causes which might have been averted, and the Navy has developed methods to limit the damage caused by bomb, shell, or torpedo and to prevent all sinkings which can be prevented. These methods constitute the modern science of *damage control*.

Damage control in ships built for war begins soon after the laying of the keel. The ship is divided into many compartments by watertight bulkheads. There may be blisters to prevent the explosion of a torpedo from reaching vital parts. A system of flooding or pumping compartments helps to keep the ship on an even keel and to maintain buoyancy. The warship is built with the paramount idea of carrying armament and using it effectively.

But in ships built for peacetime, the possibilities for damage control are more limited. Their bulkheads might be strengthened, armament for defense added, crews trained in the art of emergency repairs, guns and gun crews added.

Only Hitler has attempted to create men built for war. Even the trained navy man or the trained soldier was created for peace. He is like a merchant ship in which the conversion has been carried out as completely as possible.

moved from the other men at once. Nothing is more contagious than a neurosis while still undergoing the shock which has caused it.

Control of fatigue is usually given the attention it deserves, but its potential importance must not be forgotten. Because, in itself, fatigue may cause shock and neurosis; and the state of fatigue aggravates the effect of any mental shock. The Air Corps has learned that one aviator can stand as much as ten hours of flying, another is nervous and tired after six hours. It is the Navy's job to use to the maximum—not beyond it—all who are fit to fly, or fight.

Another example: A submarine commander reported in after eighty-four days at sea. "My crew," he said, "is in good shape. I want to keep them that way or better. I want two weeks leave for all hands."

They got it.

When Something's on Their Minds

The confessional, through the centuries, has been recognized by the Catholics as the greatest boon to mental stability. Though the institution of the confessional is not recognized by the Navy, every mature officer or man has witnessed (or experienced) the salutary effect of the frank discussion of intimate personal problems. And if the discussion leads to a solution, so much the better. The recruit, suddenly in a strange new environment, and usually assuming the new problems of physical maturity, is frequently in great need of a confessor. The chaplain and the medical officer are there, but it takes an intrepid recruit to bridge the social gulf between himself and the average chaplain or medical officer.

The chief petty officers who command the recruit companies at a naval training station are, or try to be, tough, tyrannical, and rule more by fear than by example. "Gee, I'd never have gone to him with my troubles," is the usual reaction. These are the common sentiments of replies about the period in the training station: "I was scared to death all the time" or "It was my worst time in the Navy."

Obviously, neither chaplain, medical officer, nor chief petty officer serves as confessor. The

confessor or monitor should be an experienced man with some knowledge of the Navy, and should keep himself in intimate contact and sympathy with the recruit. Navy men surveyed for physical disability or in a convalescent status would be ideal. Of course, they would need instruction.

After leaving the training station, there are always sufficient men of varied experience to act as confessors. And even though the young men need a confessor more often, the older men and officers do need one occasionally—and then imperatively. Every man in the Navy—admiral to apprentice seamen—should have someone with whom he feels at liberty to talk things over.

The system would have to be official to act. This system would not only serve to solve personal problems and get things off the chest of those confessing, it would also serve to observe the mental stability of every man in the service. Mental instability is serious to an outfit in proportion to the importance of the man whose mind becomes unstable. Frequently observations are made, yet no timely action is taken. It is only after a man has fondered with a neurosis that his chief petty officer confesses to the medical officer: "Something seems to have been bothering him," or "He's been acting screwy for a couple of weeks." Such information might have saved the man *before* a frank neurosis had developed.

Wooden ships and iron men was the boast of the Old Navy. Then came the ironclad, then the steel ship. And now we have divided the steel ship into a series of compartments intended to limit the destructive action of gun, bomb, or torpedo fire. In the condition of alert, a complicated system has been installed to maintain the equilibrium and buoyancy of the ship.

All this we have done for ships, until they are harder and harder to sink. But the means of sinking ships has kept pace with damage control. Ships continue to go down. The means of destruction of minds has also increased. Minds, too, will continue to founder. We can only do our best to keep as many minds afloat as we can by damage control.

MEDICAL TEXTBOOKS AID RUSSIANS

American medical and surgical textbooks, sent to the Soviet Union by hundreds of American physicians and medical students through Russian War Relief, are helping to prepare new doctors for work with the Red Army, it was revealed in letters sent to Russian War Relief by students in the First Kharkov Medical Institute. The Kharkov Institute, one of the largest medical schools in the world,

was moved to Chkalov when the Nazis occupied Kharkov. Classes were in full swing within a week after the faculty and student body left Kharkov.

Russian War Relief is seeking all kinds of up-to-date medical textbooks for Soviet medical students and for the Central Medical Library, in Moscow, which is used by both military and civilian doctors.—*J. Med. Soc. Co. N.Y.*

naval recruit's first day at the training station in January, 1942:

They drop us *boots* from trucks at the training station yard at about 7 A.M. and order us to pile our bags against the fence. "Fall in," is the next order, then "off with your clothes." We obey, letting our clothes fall where we stand. Dressed in our birth-day suits, we are vaccinated for smallpox and form in a line which moves slowly upstairs. In four hours I reach the doctor's office and, when my turn comes, I am given my final physical examination. Back in line again, and as we move along I get an antitetanus shot in one arm and an antityphoid in the other. Then, still standing, a hospital corpsman flattens out one arm on a board, sticks a hypodermic needle in a vein and draws out a big syringe full of blood. I move on along in line, holding a tuft of cotton over the needle hole.

At last I reach the dental offices. It's sure good to sit down, even in a dentist's chair. The dentist makes a chart of my teeth, tells me I've got to have a rotten molar out and three other teeth filled. Pleasant prospect. Back in line again, I go back to the lawn. We put on our clothes and get some dinner. After I eat I fall in a new line to have navy clothes issued. This line takes from three to six hours. I make it in four, taking time out for supper. It is midnight when I get to the barracks and am assigned a bunk. I am tired, but I can take it. Some of the young kids are blubbering like babies.

At 4:30 A.M. a chief specialist (one of Gene Tunney's race horses) turns us out. Lord, I am sleepy and my arms ache from the shots! "Double time," he shouts, and away we go for a half mile. That first day in the Navy is tough.

It may be contended that such a day as an introduction to the Navy is a good trial to weed out the weaklings. But for youngsters, some of them just seventeen years old, and for many who have left home for the first time, a day like that is initiating mental conversion with a vengeance, with an unnecessary shock.

Many humane and considerate gestures could and should be instituted. These, trivial in themselves, would not decrease efficiency but would enormously moderate the ordeal. The mere effecting of the injections and the blood-taking with the recruit seated, for example, would take no more time and prevent the epidemics of faintings which are not unusual during these operations. A day in which so much is to be accomplished cannot be made too soft. And why a half mile trot at four-thirty in the morning the very next day? There is plenty of time to get hard.

A Good Captain—a Good Ship

Damage control of the mind should be begun with that first day in the Navy. It should continue through the years of service by so influencing the environment of both men and officers to increase their resistance to mental shock.

"If there's a war, I want to be in his outfit." Sometimes, during the years of peace, I heard an enlisted man say that of an officer. It is the greatest compliment that could be paid an officer, a compliment not often heard. It signifies that the officer has created for that man the ideal of military inspiration—the wish to do his duty, if need be, his ultimate duty. If an officer can create such an inspiration in each of his men, he has accomplished a near miracle in the mental preparation of his unit for war. That officer does not need lessons in damage control of the mind.

But what are the elements by which such a near miracle is accomplished? There are four: *Loyalty, example, control of fatigue, and what may be called the institution of the confessional*. It is impossible to give these four an order of importance, because that element most lacking in any given military unit is the most important for that unit. The weakest link. . . .

Loyalty is important. Both kinds of loyalty, loyalty from the commander down to the lowest rating assures justice tempered by humanity—and it inspires loyalty from below upward. Loyalty from below upward assures attention to duty and discipline. Both kinds of loyalty together assure *esprit de corps*, high morale. From the point of view of the damage control of minds, loyalty turns the attention of the individual outward from himself to an interest in his ship or unit. His personal problems bother him less in proportion to the importance he gives to the problems of his outfit.

A good captain, if not too much hampered by bad officers and bad men, means a happy and efficient ship, and a ship remarkably free from neuroses. Conversely, an officer, particularly a commanding officer, who is egotistical, who acquires a perverted sense of values, or who is unjust and unsympathetic, is sure to endanger the mental stability of his men. And if he becomes unbalanced. . . .

As loyalty creates *esprit de corps*, example creates confidence. The officer who inspires confidence under fire is doing much for the damage control of his men's minds. If the officer is afraid, he must hide his fear, or if necessary, camouflage it with braggadocio or even facetiousness. If men waver, a word of sympathy, advice or encouragement, a good cussing-out, or a job to do, each in its proper place, may re-establish mental stability and prevent the precipitation of neuroses. Men cowering under bombardment, like dogs in a thunderstorm, usually find themselves when given the proper stimulation plus a job.

When a man actually loses his mental equilibrium—develops a neurosis—he should be re-

History of Medicine

ALEXANDER ANDERSON, M.D., 1775-1870
The First Wood Engraver in America

WALTER B. MOUNT, M.D., F.A.C.S., Montclair, New Jersey

OUR interest in Dr. Anderson was aroused by an association with Dr. Lawrance R. Thompson of Princeton University, who with Miss Helen M. Knubel is compiling an authoritative biography, each of these authors having previously published articles about Dr. Anderson.^{1,2,3} Other sources of information, which have been freely used, are the *Memorial* by Lossing,⁴ the *Life and Works* by Burr,⁵ and an article in Kelly's *Cyclopedia of American Medical Biography*.⁶

Alexander Anderson was born in New York City, April 21, 1775, at the very start of the Revolution. His father, John Anderson, a Scotsman, was a printer and publisher, who by his publications incurred the wrath of the Loyalists and was dubbed the "rebel printer." On September 15, 1776, when the British occupied New York, he fled with his family and goods. At Fort Washington the Americans seized his wagons, books, and papers, but he finally reached the home of friends in Greenwich, Connecticut, where he remained for the duration of hostilities. In 1783 he returned to New York as a printer, later becoming an auctioneer. An engraving of John Anderson from a miniature by his son is shown in Fig. 1. Fig. 2 is a similar engraving of his mother, whom he adored, a highly intelligent, religious New Englander, of strong character. She amused him and his younger brother by drawing animals, flowers, and faces. At school he studied, among other subjects, Latin and Greek and could read Latin in his old age. Early in life he began copying pictures. In a letter to Lossing he says: "I recollect being allowed an occasional peep at a considerable pile of prints, such as those issued from the London shops. Among them were Hogarth's illustrations of the careers of the *Idle and Industrious Apprentices*, which made a strong impression on my mind. These prints determined my destiny."⁴ When he was twelve years old, a schoolfellow showed him Chamber's *Cyclopedia*, in which he read an explanation of the process of engraving. He got a silversmith to roll out small copper plates from pennies, made a graver from the sharpened back-spring

of a pocket knife, and set to work. He wrote, "I did a head of Paul Jones and pleased was I when I got an impression with red oil paint in a rude rolling press which I had constructed."⁴ A blacksmith made him some tools with which he cut small ships and houses on type-metal and sold them at the newspaper offices. Fig. 3 is a photograph of his engraving tools, now in the possession of the New York Historical Society. He frequently carried tools and a block in his pockets.

Noticing that his son was copying illustrations from medical books, the father decided to make a doctor of him, and at the age of fourteen, on May 1, 1789, he entered the office of Dr. Joseph Young, who was kinder than he looks in Anderson's drawing (Fig. 4). For five years he worked with Dr. Young, seeing patients, compounding all medicines, and delivering them on foot. He found time to continue his engraving in lettering on silverware, dog collars, instruments, and cane heads, as well as in engraving maps, business cards, and book illustrations. The proceeds of this work paid for his clothes and for lectures in medicine, natural history, chemistry, physics and mechanics, law, and French. In 1793 (on January 14) he matriculated as a medical student in the Album of Columbia College. In 1794, when he was nineteen, he engraved a commencement ticket for the College. A year later Dr. Young offered to make him a partner immediately after he had obtained his license to practice on April 29, 1795. Fig. 5 is a photograph of his certificate, now in the library of the New York Academy of Medicine. The formalities attending the granting of this license are described in his diary for April, 1795:

"April 8th. I call'd upon the Mayor and express'd my wish to undergo an examination for the practice of Physic—he directed me to apply to Judge Benson—I found him not in.

"9th. I call'd upon Judge Benson who referred me to Judge Yates. Saw Judge Yates, who promis'd to appoint an Examination.

"13th. I call'd upon Judge Yates—he appointed for my Examiners Dr. Bard, Dr. Rogers, Dr. Treat, or in his place Dr. Smith—I set off immediately in the rain to notify them. Dr. Bard dissuaded me from it, and objected to my

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29, 1942.

I went to Mr. Hertell's & got the form of it—from that to a Parchment maker & got the skin—after dinner I finished it in German text.

"29th. I got Judge Yate's hand & seal to my Certificate & afterwards left it with the Attorney General.—

"30th. Call'd upon Mr. Lawrence, who promised to leave my License at my abode."⁵⁷

In 1796 he took the degree of M.D. at Columbia College, choosing "Chronic Mania"⁸ as the subject of his thesis. These ceremonies he also described in great detail.⁵⁷ In January of the next year he was engaged; in February he hired a house; and on April 15, 1797, he married Nancy Van Vleck. On the wedding ring he engraved "United in Heaven." He then became a publisher and bookseller for five months, but he made no money and had his father auction off his 7,000 books.

In 1795 when the yellow fever broke out in New York, Dr. Anderson became house surgeon at Bellevue Hospital, at a salary of \$4.00 a day, from August 24 to November 11. Of 238 patients admitted, 99 were cured and 137 died. The staff consisted of the steward and his wife, three nurses, and two workmen; at times two other physicians assisted. The patients were brought to the hospital by sailboat. Anderson

uncertainty and experiment, he was unwilling to bear the responsibility of a professional healer whose prognoses might often be unfulfilled.⁴ He himself had a mild attack of yellow fever. In the spring of 1799, he spent several months in St. Vincent with an uncle who was King's Botanist on the Island. He declined a lucrative offer there and returned to New York to take up his engraving again. He soon married the sister of his lost wife and had a happy home life with her. They had one son and five daughters. The son, John, became a physician but died in 1836. The daughters all married.

As we have said, Anderson did much engraving while still studying medicine and continued to do more later. His first work was on copper or type-metal. In 1793 he seems to have used wood for the first time. Boxwood was the only satisfactory wood, and that was prone to crack. He found that the wood of the pear-tree was not suited for fine work. In 1794 he used wood more frequently, especially after reading a sketch of the life and works of the English engraver, Thomas Bewick (1753-1828), and seeing his illustrations of birds and quadrupeds. After 1812 he used only wood. He copied

Bewick's style throughout his life and did innumerable charming small engravings, often full of pathos or humor. His larger engravings, like those in Shakespeare's works, are well spoken of. For years he had very little competition, but as the demand for this kind of illustration grew, many others took up the work. Anderson had four special pupils who worked under him for some time; his second pupil, William Morgan, became his favorite draughtsman. During his life he produced nearly ten thousand separate illustrations which had appeared in perhaps six hundred different books and pamphlets.⁵ One of these is an engraving for the St. Nicholas dinner of the New York Historical Society on December 6, 1810⁶ (Fig. 7). In 1864 Dr. Anderson, then in his ninetieth year, made a similar engraving for another St. Nicholas dinner. He was a member of the old Academy of Fine Arts and a very early member of the Academy of Design.

Anderson was shy, reticent, and modest. He was short, "compactly built, with mild and beautiful dark grey eyes and a face ever beaming with indices of kindly feeling and serenity of spirit." Fig. 8 is a drawing of Anderson at the age of 44; "and for many years that venerable

as physician to the New York Dispensary at a salary of \$1,000, but he declined the offer.

In 1798 New York was again visited by yellow fever. On July 3 Anderson's three-months-old son died. On August 31 he again took his place at Bellevue Hospital. On September 8 his brother John died, on September 12 his father; the next day his wife. He left Bellevue after only ten days and was appointed physician for the poor.

On September 21 he lost his mother, on September 24 his mother-in-law, and on October 12 his sister-in-law. After experiencing the deaths of seven relatives in fifteen weeks, he decided to abandon medicine for engraving.

A prominent trait in his character was conscientiousness. He could do nothing which conscience did not approve. Because the practice of medicine necessarily involved frequent

FIG. 13. "Till Death Us Do Part." Copied by Anderson from a tailpiece by Thomas Bewick for *The Looking Glass*; recut by Anderson for his own pleasure after he had leisure in his old age. Engraving by Dr. Anderson after his ninetieth year. After Thomas Bewick. From *A Memorial of Alexander Anderson, M.D.*, by Benson J. Lossing. 1872.

FIG. 14. "Dangerous Crossing." Anderson seemed to enjoy Thomas Bewick's little tailpieces which were obviously or potentially humorous. This is from a cut in Bewick's *Quadrupeds* which Anderson copied in his old age. Engraving by Dr. Anderson after his ninetieth year. After Thomas Bewick. From *A Memorial of Alexander Anderson, M.D.*, by Benson J. Lossing. 1872.

FIG. 15. Portrait of Dr. Anderson at the age of ninety-two, drawn by August Will and engraved by Elias J. Whitney. From *Life and Works of Alexander Anderson, M.D.*, by Frederic M. Burr. 1893.

FIG. 16. Illustration for Walter Scott's *Lay of the Last Minstrel*, Dr. Anderson's last finished engraving. From *A Memorial of Alexander Anderson, M.D.*, by Benson J. Lossing. 1872.

uncertainty and experiment, he was unwilling to bear the responsibility of a professional healer whose prognoses might often be unfulfilled.⁴ He himself had a mild attack of yellow fever. In the spring of 1799, he spent several months in St. Vincent with an uncle who was King's Botanist on the Island. He declined a lucrative offer there and returned to New York to take up his engraving again. He soon married the sister of his lost wife and had a happy home life with her. They had one son and five daughters. The son, John, became a physician but died in 1836. The daughters all married.

As we have said, Anderson did much engraving while still studying medicine and continued to do more later. His first work was on copper or type-metal. In 1793 he seems to have used wood for the first time. Boxwood was the only satisfactory wood, and that was prone to crack. He found that the wood of the pear-tree was not suited for fine work. In 1794 he used wood more frequently, especially after reading a sketch of the life and works of the English engraver, Thomas Bewick (1753-1828), and seeing his illustrations of birds and quadrupeds. After 1812 he used only wood. He copied

Bewick's style throughout his life and did innumerable charming small engravings, often full of pathos or humor. His larger engravings, like those in Shakespeare's works, are well spoken of. For years he had very little competition, but as the demand for this kind of illustration grew, many others took up the work. Anderson had four special pupils who worked under him for some time; his second pupil, William Morgan, became his favorite draughtsman. During his life he produced nearly ten thousand separate illustrations which had appeared in perhaps six hundred different books and pamphlets.⁵ One of these is an engraving for the St. Nicholas dinner of the New York Historical Society on December 6, 1810⁶ (Fig. 7). In 1864 Dr. Anderson, then in his ninetieth year, made a similar engraving for another St. Nicholas dinner. He was a member of the old Academy of Fine Arts and a very early member of the Academy of Design.

Anderson was shy, reticent, and modest. He was short, "compactly built, with mild and beautiful dark grey eyes and a face ever beaming with indices of kindly feeling and serenity of spirit." Fig. 8 is a drawing of Anderson at the age of 44; "and for many years that venerable

head was surrounded as by a halo, with white locks and beard. His voice was soft and low. He was genial in thought and conversation and had a quick perception of genuine humor. To him this world was a delightful place to live in because it was a reflex of his own sweet spirit. He was extremely regular and temperate in all his habits." Thus writes Lossing,⁴ who knew him. Fig. 9 was engraved by Dr. Anderson in his eighty-first year, after one of the very early daguerreotypes.^{2,6} He objected seriously to the whole procedure. Another portrait (Fig. 10) appears as the frontispiece of Lossing's book.⁴ Fig. 11 is Anderson's business card issued when he was eighty-four years old in 1859. Several engravings were done after his ninetieth year. Fig. 12 is one of these. Fig. 13 has been called "Till Death Us Do Part," and Fig. 14 "Dangerous Crossing." Fig. 15 is a portrait of Dr. Anderson at the age of ninety-two, appearing as the frontispiece of the biography by Burr.⁵ Fig. 16 is Anderson's last finished engraving, an illustration for Walter Scott's *Lay of the Last Minstrel*.

Dr. Anderson was a good miniature painter and in his early life was frequently employed in that capacity. He painted on ivory the portraits of all his daughters when they were young women.⁵ He played the violin and the clarinet. He taught Washington Irving to play the latter. Irving said of him: "He was handsome, artless, and full of good humor, and as gentle as a woman."⁴ In 1867 Mr. Evert A. Duyckinck said that although "there was a partial loss of hearing, his mental faculties were still vigorous, his memory clear, his judgment sound. He conversed freely and talked like one who had thought much in retirement, who had concentrated his thoughts, and made himself master of his reading. He had a copy of the *Orations of Cicero* in the original. It was a well-battered school book, which he said he had recently been engaged in reading without

the aid of a translation, with occasional resort to a dictionary. His comments showed discrimination and judgment of his own. I remember his remark on old age as a thing hard to be understood." The next year he was offered honorary membership in the New York Historical Society.⁴ During his last years he engraved many pictures for his own amusement, taking that method of preserving any design that happened to strike his fancy. He had a little workshop built in the yard, and there he would keep himself busily employed. He never considered his old blocks worth preserving and frequently cut up the larger ones to kindle the fire. He would never consent to receive more than what he considered a fair price for his work, even when a larger sum had been agreed upon. Six months before his death he drew a picture upon a block and had partly engraved it,⁵ but he quietly passed away on January 17, 1870, before the engraving was completed.

MERGER OF PHARMACEUTICAL COMPANIES

A merger of two companies in the field of ethical pharmaceuticals (drugs dispensed largely on physicians' prescriptions) has been announced by James Hill, Jr., president of Sterling Drug Inc., of which both are affiliates.

Under the merger, Winthrop Chemical Company, Inc., has absorbed Alba Pharmaceutical Company, Inc., and has taken over Alba's assets, property, trade-marks, and good will.

"Although Alba ceases to exist," Mr. Hill said, "its research and manufacturing facilities in Rens-

selaer, New York, have been consolidated with those of Winthrop. Its marketing policies remain undisturbed. Dr. J. Mark Hiebert, medical director of Alba, becomes assistant to Dr. Theodore G. Klumpp, Winthrop president, devoting himself largely to that company's expanding program of medical research. Other Alba personnel will be absorbed by the surviving company."

As a result of the merger, Fairchild Brothers and Foster, a wholly owned subsidiary of Alba, has become a wholly owned subsidiary of Winthrop.

Case Reports

SYSTEMIC TOXIC EFFECTS CAUSED BY TOPICAL APPLICATION OF SULFANILAMIDE IN THE PERITONEAL CAVITY

MARTIN J. LOEB, M.D., New York City

ACUTE hemolytic anemia resulting from sulfanilamide was first described by Harvey and Janeway.¹ Since then many others have from time to time reported cases of acute hemolytic anemia as a toxic manifestation of the sulfa drugs.

Long, Bliss, and Feinstein,² in their analysis of patients treated with sulfa drugs, found hemolytic anemia occurring in 2.9 per cent in adults and 8.9 per cent in children. They studied 307 adult cases and 101 children.

Fox and Ottenberg³ reported 4 cases of acute hemolytic anemia following the use of sulfonamide drugs, of which 2 cases were fatal. Their data and scientific analysis are an excellent presentation of the pathologic processes resulting from the toxic manifestations of the drugs.

There are no reports in the literature of toxic effects produced by sulfanilamide applied intraperitoneally. As a matter of fact, from the literature one has the impression that the introduction of sulfanilamide in the peritoneal cavity is a very useful but harmless procedure. It is for this reason that this case is reported.

Thompson, Brabson, and Walker,⁴ in their paper on the "Intra-Abdominal Application of Sulfanilamide in Acute Appendicitis," state: "One has noticed no definite toxic effects from the use of the drug administered in this fashion except some cyanosis, which, though not a constant feature, is usually evident. The nausea and vomiting, if present, have not been sufficiently distinguishable from that to be expected in a convalescent from an appendectomy. There have been no cases of leukopenia or agranulocytosis, but there was one case of jaundice which was felt to be secondary to the streptococcus peritonitis, as it disappeared under the continued administration of sulfanilamide by mouth."

Crile⁵ in his paper on the "Local Use of the Sulfonamide Drugs," poses four questions on the use of the drug. We are interested in his first question: "What dangers attend the too rapid absorption and consequent overdosage of the drug?" His answer is that there is little or no danger from the drugs when they are implanted in wounds. He further states that when the sulfonamide drug is implanted in the peritoneal cavity, absorption may be more rapid than that following its application to wounds, but the blood levels still do not rise so fast or to levels so high as those following the oral administration of equivalent doses. Crile asserts that it is probably dangerous to implant more than 15 Gm. of sulfanilamide in the peritoneal cavity at any one time.

Estrin⁶ reports that in 30 cases of peritonitis complicating appendicitis there were no toxic manifestations from the application of the drug except some mild cyanosis in a few instances.

Mueller⁷ reported a series of cases in which he noticed no systemic toxic effects from the topical use of the drug. The absorption of the drug from the peritoneal cavity depends upon the amount of the drug introduced. Generally speaking, the absorption is very much slower than it is when the drug is given by mouth.

A report of the case is as follows:

Case Report

A. A., 19-year-old boy, was admitted to the hospital on July 25, 1941. The patient was ill for one day before admission. He was operated on under spinal anesthesia and a retrocecal gangrenous appendix surrounded by loops of ileum was found. There was also free pus. The appendix was removed and 8 Gm. of sulfanilamide introduced. The abdominal cavity was drained.

The day after operation, the patient had a temperature of 101.4 F. but showed no untoward symptoms. On the second postoperative day, the patient developed an icteric tint in the eyes and skin. Examination of the abdomen was negative. On the third postoperative day, the patient had marked jaundice with bile in the urine. His hemoglobin went down from 106 per cent preoperatively and 5,300,000 red cells to 70 per cent hemoglobin and 3,550,000 red cells. The patient continued to get worse. He became yellow, pale, and vomited occasionally. He looked toxic.

On the fourth day postoperatively, his hemoglobin went down to 32 per cent and the red blood cells to 1,600,000. He was given a transfusion on that day. After the transfusion, the patient began to rally and to improve gradually. His jaundice disappeared, and his hemoglobin and red blood cells coincidentally rose. On his discharge, about eighteen days postoperatively, the patient had a hemoglobin of 82 per cent and 4,500,000 red cells. It is worth noticing that on the day when his red blood count was the lowest—1,600,000—his white count rose to 28,000 and the young forms to 11 per cent. With a rise of hemoglobin and red blood cells, the young forms diminished. The effect of the drug is therefore a destruction of red cells and not of the hematopoietic system. His icteric index taken on the fourth day postoperatively was 62.4. The Van den Bergh direct was immediate; the indirect, 5 to 8 units. The excretion of hippuric acid calculated on the basis of benzoic acid was 2.31 Gm., slightly below normal (the normal being 3 Gm. of hippuric acid excreted several hours after the intake of 6 Gm. of sodium benzoate). Apparently there was no liver damage. At any rate, whatever liver damage did exist was undoubtedly secondary to the anemia caused by the drug.

From the Surgical Service of Dr. Loeb at the Bronx Hospital.

TABLE 1.—BLOOD EXAMINATIONS (A. A. Hosp. 124598)

Date	July 25	July 27	July 28	July 30	July 31	Aug. 1	Aug. 4	Aug. 11
Hemoglobin	106%	90%	70%	32%	44%	48%	57%	82%
Erythrocytes	5.3M	4.3M	3.55M	1.61M	2.24M	2.6M	2.82M	4.4M
Leukocytes	13,500	15,800	17,400	28,100	18,500	13,400	11,000	9,400
Neutrophils	87%	78%	78%	58%	57%	65%	58%	76%
Eosinophils	1%	1%	2%
Basophils	2%	...	1%	...
Band Forms	...	5%	...	4%	7%	4%
Lymphocytes	9%	14%	14%	15%	12%	12%	2%	22%
Monocytes	4%	3%	8%	10%	13%	10%	31%	...
Young Forms	11%	5%	6%	7%	...

Summary

The topical application of sulfonamide is not always free from complications. The toxic manifestations in this case began on the second postoperative day and reached their peak on the fourth postoperative day, after which the symptoms began to abate and the patient improved.

It is possible that the transfusion hastened the process of recovery.

ISOLATED FRACTURE OF THE FIRST RIB

Report of Three Cases, Including One with Pseudarthrosis Formation

ABRAHAM G. COHEN, M.D., New York City

IN THE course of routine roentgenographic examinations of the chests of selectees for military service, conducted primarily for the detection of tuberculous lesions, other abnormalities are occasionally disclosed. In a period of two weeks, during which time approximately three thousand examinations were made, 3 cases of isolated fracture of the first rib were detected. In each instance the individual affected was unaware of any symptoms referable to this condition.

Case Report

Case 1.—J. B., aged 22, was noted to have a fracture of the right first rib with moderately extensive callus formation (Fig. 1). Upon questioning, he recalled having been struck by a crane in the right upper chest about three months previously. He had experienced some local pain for several days and on the night after the accident had expectorated a small amount of blood. He had not sought medical attention. At the time of the examination, there were no symptoms or abnormal physical signs.

Case 2.—A. M., aged 25, was found to have a fracture of the left first rib with considerable overriding of the fragments; there was no evidence of callus formation (Fig. 2). On questioning, the only possible causative factor revealed was the fact

that his occupation consisted in carrying heavy cases of bottled beverages, usually on the left shoulder. He had never noticed pain in this region.

Case 3.—R. W., aged 23, was found to have a linear break in the continuity of the right first rib; the edges were exceptionally smooth. There was no evidence of callus formation (Fig. 3). He gave no history of direct or indirect trauma nor did he recall any previous pain. It was the impression of several roentgenologists who examined the film that the picture was that of an old fracture with resultant pseudarthrosis.

Discussion

Because of its relatively protected position, as well as its smallness in size, the first rib is fractured much less frequently than most of the others.¹ Hinton and Steiner² analyzed a large series of rib fractures and found the first rib to have been affected 14 times out of 393 on the right and 8 out of 414 on the left. Breslin,³ reviewing the literature through 1933, noted 27 cases of isolated fracture of the first rib and added 5 of his own. Since then about 26 additional cases have been reported⁴⁻¹⁷ although the literature in some languages has not been reviewed. In 4 cases both first ribs were fractured.^{4,9,13,17}

It is generally agreed that this uncommon fracture is not ordinarily caused by direct trauma. Lane is quoted^{2, 13} as having mentioned 3 possible mechanisms: (1) indirect violence, (2) direct force from behind, and (3) force through the manubrium sterni. Sudden tension on the rib by pull of the neck

From the U.S. Army Induction Station, Trenton, New Jersey.

Major, Medical Corps, U.S. Army, now with 210th General Hospital.

FIG. 1. Case 1. Fracture of right first rib with callus formation

FIG. 2. Case 2. Fracture of left first rib with overriding of fragments

muscles, particularly the scalenus anticus, frequently is mentioned as a cause.^{3,7,14} In the cases reported here, the fracture in one seemed to have been the result of a direct blow to the upper anterior chest. In another, a possible causative factor was the muscle strain incidental to the patient's having carried heavy weights on his shoulder. In the third, no cause is apparent.

Although in most instances pain is noted, this symptom is frequently absent or is disregarded by the patient, as is so strikingly illustrated by the 3 cases reported. The lesion rarely presents abnormal physical signs and ordinarily is detected only on roentgenographic examination, usually made either routinely or with other abnormalities in mind. Even then, it may be missed unless special views are taken, since the first rib often is obscured at least partly by overlying soft or bony structures.

In addition to the complications common to fractures of any rib, such as pneumothorax, fracture of the first rib, because of its location, may result in other disturbing sequelae. Oldfield⁹ described a case resulting in fatal puncture of the subclavian artery. The formation of callus in an already crowded space may lead to encroachment upon nerve trunks. Thus, Outland and Hanlon¹³ reported a case in which evidence of brachial plexus damage appeared a few months after the injury and Breslin⁴ noted the appearance of a Horner's syndrome after seven weeks. In none of the 3 cases reported herein was there evidence of injury to a nerve trunk. None of the films showed a pneumothorax, and the costophrenic sinuses in all cases were sharp and clear.

Von Sassen¹² described a case in which the history suggested that the first rib had been injured three years previously as a result of spear-throwing. The roentgenogram showed a line of cleavage through the rib; the edges of the fragments were smooth and the appearance was that of a typical pseudarthrosis. This is of interest in view of Case 3. The *Index Medicus* lists another case¹⁷ the text of which could not be obtained.

FIG. 3. Case 3. Pseudarthrosis formation in right first rib probably due to previous fracture.

Summary

1. In the course of routine roentgenographic chest examinations, 3 cases of isolated fractures of the first rib were noted.
2. In one of the cases, the roentgen picture was that of pseudarthrosis.
3. In no case was the patient aware of symptoms referable to this condition.
4. Fractures of the first rib are uncommon; they are rarely caused by direct trauma.
5. Injury to the underlying nerve trunks or large blood vessels is an occasional complication.

TWO CASES OF TYPHOID FEVER TREATED WITH SULFAGUANIDINE

D. D. ALTHOUSE, M.D., and MARY KIRKWOOD, M.D., Auburn, New York

THE following two cases of typhoid fever were admitted to the Auburn City Hospital Medical Service, September 5, 1941, from one of the small country villages.

Case 1.—G. B., aged 11 years, became ill August 21, with fever and diarrhea, followed eight days later by a rash. Two days before admission *Bacillus typhosus* was cultured from the stools, and the Widal test was positive for *B. typhosus* infection.

On admission the boy was acutely ill, with flushed face, temperature 103 F. (R), pulse 80. The abdomen was moderately distended, and there was generalized tenderness to palpation. A papular rash appeared on the abdomen and thighs.

On September 6, the stools were positive for *B. typhosus* culture. The patient's condition continued to be unchanged, except for an increase in temperature and more abdominal distention.

On September 11, the patient was given sulfaguanidine 0.5 Gm. every four hours, day and night. The dose was reduced to every six hours on September 12 because of a fall in the leukocyte count, and on September 14 it was stopped entirely.

Clinically the case improved after the administration of the drug, as evidenced by the downward trend of the temperature curve and less abdominal distention and tenderness.

The stools, which were positive daily, became negative for *B. typhosus* on September 18, and with the exception of one day, September 20, remained negative until October 1. The sulfaguanidine was again given in doses of 0.5 Gm. every four hours and reduced to every six hours on October 3 and to every eight hours on October 4, being stopped completely on October 5. Eight stool examinations, repeated every second day, were reported negative, following the administration of the sulfaguanidine.

On October 9 the patient had sufficiently recovered to be up in a chair and also to be placed on a regular diet.

Case 2.—The history of the second case of ty-

phoid treated with sulfaguanidine is as follows:

H. B., aged 13 years, became ill August 22, 1941, with diarrhea and fever, which continued until his admission to the hospital on September 5.

On admission the patient was seriously ill, with a temperature of 105 F. (R), pulse 100, abdomen moderately distended with generalized tenderness, and papular erythematous rash over the thighs and abdomen.

On September 6, his stools gave a positive culture for *B. typhosus* and a negative one for the para organisms. A positive Widal test for *B. typhosus* was taken.

The patient daily became more ill, with chills and a septic type of temperature. On September 11, it was decided to give him sulfaguanidine, 0.5 Gm. every four hours day and night. After twenty-four hours, this was reduced to every six hours, and in forty-eight hours administration of the drug was stopped because of a decrease in his urinary output. At this time the patient was clinically improved, with less abdominal distention and tenderness and a downward temperature curve. Daily cultures of the stools and urine were positive until September 15. The stools became negative on this date, repeated cultures of both the stools and urine remaining negative.

The patient improved daily and was allowed out of bed on October 9. He was discharged on October 20.

It is interesting to note that in this case the sulfaguanidine apparently had no effect per se on the temperature. It was only after the stools became negative that the temperature curve turned downward and fell gradually to normal by lysis.

We feel from these two cases that sulfaguanidine has a definite value in the treatment of typhoid fever, for it evidently shortened the duration of these cases, the course of the disease apparently being reduced by the sterilization of the intestines.

STUTTERING AGGRAVATED BY SERVICE IN THE ARMY

According to Dr. James Sonnett Greene, medical director for the National Hospital for Speech Disorders in New York City, the number of breakdowns of service men who stutter is increasing. This is due, Dr. Greene says, to the fact that the Army continues to put stutters in active service instead of non-combatant duty.

In 1942 the hospital treated the largest number of patients in its history, a total of 3,515. Of these the

majority were stutters, and a growing number of the patients are soldiers.

Dr. Greene pointed out that cases of stuttering are chiefly due to nervous and mental disorders, which render the sufferer as unfit for service as men with more obvious physical defects. Not only is the stutterer subject to permanent impairment if kept on in the Army, but also he is not in a position to be of service from a military standpoint.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

Nervous Conditions Associated with Warfare

A POSTGRADUATE lecture arranged for the Tompkins County Medical Society, to be held Tuesday evening, March 16, at 8:30 P.M., at Tompkins County Memorial Hospital in Ithaca.

"Nervous Conditions Associated with Warfare" is the title of the lecture, to be given by Foster

Kennedy, M.D., professor of clinical medicine (neurology), Cornell University Medical College, New York City. It is a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of New York.

Treatment of Common Diseases

UNDER the direction of Dr. Clayton W. Greene of the University of Buffalo School of Medicine, a series of two lectures was presented in February to the Madison County Medical Society on the "Treatment of Common Disease." The lectures took place at 8:30 P.M. in the Hotel Oneida in Oneida, New York. Subjects and speakers were as follows:

February 11—"The Management of Arthritis, Acute and Chronic"

L. Maxwell Lockie, M.D., professor of therapeutics, University of Buffalo School of Medicine.

February 23—"Renal Lesions Simulating Other Maladies"

Clayton W. Greene, M.D., professor of medicine, University of Buffalo School of Medicine

Medical Aspects of Chemical Warfare

A POSTGRADUATE course in the "Medical Aspects of Chemical Warfare" was held on February 16 for the Tompkins County Medical Society in the Tompkins County Memorial Hospital in Ithaca.

The course was arranged by the Council Committee on Public Health and Education in

cooperation with the Health Preparedness Commission of the State War Council. Speakers included: Neal E. Artz, Ph.D., associate professor of physiological chemistry, Syracuse University College of Medicine; and John J. Bourke, M.D., state medical officer, New York State Health Preparedness Commission.

DIMOUT LOWERS DRIVERS' VISION, DEVICE DISCLOSES

Driver vision is reduced 40 to 60 per cent by the dimout, the New York University Center for Safety Education, at 8 Fifth Avenue, reported following examination of 1,000 drivers with the dimometer, a laboratory machine that simulates a dimmed-out street.

The dimometer, designed by Dr. Charles C. Hawkins, research assistant at the center, is a scale reproduction of a typical cross-town block. Housed in a box three feet long by eighteen inches wide, it contains a street, sidewalks, an intersection, an alley, five cars, five pedestrians, and three street lamps. The scale is one inch to six feet.

Lighting in the dimometer is controlled by a rheostat and was determined by the candlepower average of typical streets.

The subject looks through a reducing lens at the street scenes and is graded according to the number of true-to-scale pedestrians he sees cross the block on which he is theoretically driving. The subject scores only if he sees the pedestrian before he crosses the street. Less than 10 per cent of the thousand persons tested, all New York City civil service

employees, succeeding in making perfect scores.

Dr. Herbert J. Stack, director of the center, said the driver's peripheral vision—the ability to distinguish objects at angles from the eyes—is practically zero in the dimout. For this reason, he said, pedestrians should be particularly cautious before stepping from the curb into the line of traffic.

Even the most alert driver would be no more than 80 per cent efficient in dimout conditions, Dr. Stack said, emphasizing the necessity for lowered speeds.

The Center for Safety Education estimates that the rate of traffic deaths is 20 per cent higher on the basis of total vehicle-miles driven.

"There is a danger zone approximately forty feet in front of any vehicle proceeding at twenty miles an hour," Dr. Hawkins said. The "danger zone" is determined by the reaction distance for the driver to see the pedestrian and set his brakes—twenty feet—and the distance needed to stop the vehicle—another twenty feet—he explained. At thirty miles an hour, probably more nearly the average speed of New York taxicabs, the danger zone is eighty feet.

TWO CASES OF TYPHOID FEVER TREATED WITH SULFAGUANIDINE

D. D. ALTHOUSE, M.D., and MARY KIRKWOOD, M.D., Auburn, New York

THE following two cases of typhoid fever were admitted to the Auburn City Hospital Medical Service, September 5, 1941, from one of the small country villages.

Case 1.—G. B., aged 11 years, became ill August 21, with fever and diarrhea, followed eight days later by a rash. Two days before admission *Bacillus typhosus* was cultured from the stools, and the Widal test was positive for *B. typhosus* infection.

On admission the boy was acutely ill, with flushed face, temperature 103 F. (R), pulse 80. The abdomen was moderately distended, and there was generalized tenderness to palpation. A papular rash appeared on the abdomen and thighs.

On September 6, the stools were positive for *B. typhosus* culture. The patient's condition continued to be unchanged, except for an increase in temperature and more abdominal distention.

On September 11, the patient was given sulfaguanidine 0.5 Gm. every four hours, day and night. The dose was reduced to every six hours on September 12 because of a fall in the leukocyte count, and on September 14 it was stopped entirely.

Clinically the case improved after the administration of the drug, as evidenced by the downward trend of the temperature curve and less abdominal distention and tenderness.

The stools, which were positive daily, became negative for *B. typhosus* on September 18, and with the exception of one day, September 20, remained negative until October 1. The sulfaguanidine was again given in doses of 0.5 Gm. every four hours and reduced to every six hours on October 3 and to every eight hours on October 4, being stopped completely on October 5. Eight stool examinations, repeated every second day, were reported negative, following the administration of the sulfaguanidine.

On October 9 the patient had sufficiently recovered to be up in a chair and also to be placed on a regular diet.

Case 2.—The history of the second case of ty-

phoid treated with sulfaguanidine is as follows:

H. B., aged 13 years, became ill August 22, 1941, with diarrhea and fever, which continued until his admission to the hospital on September 5.

On admission the patient was seriously ill, with a temperature of 105 F. (R), pulse 100, abdomen moderately distended with generalized tenderness, and papular erythematous rash over the thighs and abdomen.

On September 6, his stools gave a positive culture for *B. typhosus* and a negative one for the para organisms. A positive Widal test for *B. typhosus* was taken.

The patient daily became more ill, with chills and a septic type of temperature. On September 11, it was decided to give him sulfaguanidine, 0.5 Gm. every four hours day and night. After twenty-four hours, this was reduced to every six hours, and in forty-eight hours administration of the drug was stopped because of a decrease in his urinary output. At this time the patient was clinically improved, with less abdominal distention and tenderness and a downward temperature curve. Daily cultures of the stools and urine were positive until September 15. The stools became negative on this date, repeated cultures of both the stools and urine remaining negative.

The patient improved daily and was allowed out of bed on October 9. He was discharged on October 20.

It is interesting to note that in this case the sulfaguanidine apparently had no effect per se on the temperature. It was only after the stools became negative that the temperature curve turned downward and fell gradually to normal by lysis.

We feel from these two cases that sulfaguanidine has a definite value in the treatment of typhoid fever, for it evidently shortened the duration of these cases, the course of the disease apparently being reduced by the sterilization of the intestines.

STUTTERING AGGRAVATED BY SERVICE IN THE ARMY

According to Dr. James Sonnett Greene, medical director for the National Hospital for Speech Disorders in New York City, the number of breakdowns of service men who stutter is increasing. This is due, Dr. Greene says, to the fact that the Army continues to put stutterers in active service instead of non-combatant duty.

In 1942 the hospital treated the largest number of patients in its history, a total of 3,515. Of these the

majority were stutterers, and a growing number of the patients are soldiers.

Dr. Greene pointed out that cases of stuttering are chiefly due to nervous and mental disorders, which render the sufferer as unfit for service as men with more obvious physical defects. Not only is the stutterer subject to permanent impairment if kept on in the Army, but also he is not in a position to be of service from a military standpoint.

Ginsburg, with discussion by Dr. Samuel Gitlow; "Pernicious Anemia with Cord Symptoms," by Dr. Max Weiss and Dr. Nathan Rosenthal; "Meningitis of Otic Origin: Mastoidectomy—Recovery," by Dr. William M. Bronson, with discussion by Dr. Hyman D. Silver; "Colectomy," by Dr. Louis Sheinman and Dr. Benjamin Sherwin.

. . .

The Bronx Otolaryngological Society, Inc., will meet as the guests of the Otolaryngological Section, Brooklyn Academy of Medicine and Medical Society County of Kings, at Kings County Medical Building on March 10 at 9:00 p.m., to hear the following program: "Recent Concepts of Rhinoplasty in Nasal Cartilage Deformities," by Dr. Abraham P. Matusow, of the Bronx, with discussion by Dr. Samuel Fomon (by invitation); "Petrositis," by Dr. Philip Sacks, of the Bronx, with discussion by Dr. Robert L. Moorhead, of Brooklyn.

Broome County

A new method of treating burns, developed especially for use on the battlefield, was explained by Dr. Kenneth L. Pickrell, instructor in surgery at the Johns Hopkins Hospital, Baltimore, to members of the Broome County Medical Society at their meeting in the Binghamton City Hospital on February 9.

Called the "film treatment," the method employs "pre-formed sulfadiazine films or bandages" which can be applied to burns or injured surfaces, Dr. Pickrell said.

"Content of the newest of sulfa drugs is so high," he said, "that it is impossible for bacteria or germs to develop or spread." It is now being used in all the larger medical centers, he stated.*

Dutchess County

Dutchess County Medical society met at the Hudson River State Hospital on February 10 at 8:30 p.m. Dr. Emil A. Stoller, the new president, was in charge. The scientific program included a paper on "Surgical Treatment of Coronary Disease," by Dr. Samuel A. Thompson, of New York City, and Dr. Milton J. Rasbeck.*

. . .

The following is a list of the committees for the county society for the ensuing year:

Public Health, Public Relations, and Publicity—Dr. Scott Lord Smith, Dr. E. F. Powell, Dr. Gilbert MacKenzie.

Legislative—Dr. Earle W. Voorhees, Dr. C. O. Davison, Dr. H. P. Carpenter.

Library—Dr. A. L. Peckham, Dr. Phebe Brown, Dr. W. F. Locke.

Economics—Dr. Donald Malven, Dr. A. W. Thomson, Dr. Max M. Simon, Dr. Frank Gagan, Dr. Howard Townsend.

Cancer—Dr. Helen Palliser, Dr. Jane Baldwin, Dr. George Lane, Dr. John McGrath.

Program—Dr. W. H. Meyer, Dr. J. M. Jacobus, Dr. Clifford A. Crispell, Dr. John Kerrigan, Dr. Leo Murphy.

T. E. R. A. (City)—Dr. John I. Cotter, Dr. Joseph Cummings, Dr. F. Harold Crispell, Dr. James J. Toomey, Dr. F. M. Hedgecock.

T. E. R. A. (County)—Dr. S. E. Appel, Dr. Walter Wicks, Dr. George Jennings, Dr. E. Gordon MacKenzie, Dr. G. S. Tabor.

* Asterisk indicates that item is from local newspaper.

Medical Expense Fund, Inc., of New York, is ready to serve groups in Dutchess County, having become well established in the Hudson Valley area which it embraces, according to Dr. Chester O. Davison, of Poughkeepsie, local trustee of the corporation.

Dr. Davison pointed out that the Medical Expense Fund, Inc., has now been established for three years. It has been endorsed by the Dutchess County Medical Society and by the Medical Society of the State of New York.*

. . .

Dr. W. G. Thompson has established an office for the general practice of medicine and surgery in the former office of Dr. H. S. Bulkeley in Rhinebeck.

Dr. Thompson is a graduate of Duke University School of Medicine. He served an internship at White Plains Hospital and recently completed a general residency at that institution.

Essex County

At a special meeting of the Essex County Public Health Committee held on February 3 a venereal disease control plan for the county was considered. Attending the session were Dr. James H. Lade, director of the Division of Syphilis Control of the New York State Department of Health; Dr. S. A. Volpert of Lake Placid, president of the Essex County Medical Society; and Dr. Glidden, secretary of the society.*

. . .

Of the seven physicians that Essex County declared available by the Office of Procurement and Assignment, now commissioned officers are: Dr. James Walsh, of Ticonderoga; Dr. Simpson, of Port Henry; Dr. V. F. Krakes, of Keeseville; and Dr. H. T. Booth, of Schroon Lake.

Dr. Knapp, of Ticonderoga, has been appointed to head the new tuberculosis committee for Essex County.

. . .

Officers of the county society are: president, Dr. S. A. Volpert; vice-president, Dr. George Knapp; secretary and treasurer, Dr. James E. Glavin; censors, Dr. A. L. Hayes; Drs. John Miller and T. J. Cummins; delegate to State Convention, Dr. J. A. Geis; alternate delegate to State Convention, Dr. T. R. Cummins; delegate to the Fourth District Branch, Dr. Edwin C. Johnson; alternate delegate to the Fourth District Branch, Dr. Robert H. Gray.

—J. E. GLAVIN, M.D.

Fulton County

Dr. Arthur C. Hagedorn of Gloversville, who has rounded out a half century of service in his profession, was given a testimonial dinner at the Hotel Johnstown on January 27, by members of the Fulton County Medical Society.

He is one of the few M.D.'s in his part of the state to attain this distinction. During the dinner and meeting, officers were elected for the ensuing year.

The program was opened with a dinner served at 6:30 p.m., over which Dr. A. R. Wilsey, of Gloversville, president of the society, presided.

Following the dinner Dr. Wilsey, a great nephew

Medical News

War Sessions by College of Surgeons

NEW developments in military and civilian medical and hospital service will be brought to members of the medical profession at large and to hospital representatives through a series of twenty War Sessions, beginning March 1, to be held throughout the United States under the sponsorship of the American College of Surgeons, with the cooperation of other medical organizations and of the Federal medical services.

Each War Session will consist of an all-day program, lasting from 9:00 A.M. to 10:00 P.M., including luncheon and dinner conferences. There will be eight meetings in each session, four of which will be open to the entire assembly, with the remainder divided into two meetings each for physicians and for hospital representatives. Subjects will be similar in the different localities, but some of the speakers will be different in the different states and service commands. Nationally known representatives of the United States Army, the United States Navy, the United States Office of Civilian Defense, the United States Procurement and Assignment Service, and the United States Public Health Service will address the meetings and will lead discussions, in addition to participation by prominent leaders in civilian medical practice and hospital service.

Topics to be discussed relating to military medicine will include care of the ill and injured in combat zones and after their evacuation. The newer types of injuries encountered in this war, such as crush and blast injuries, will be especially considered,

together with prevention and treatment of infections, and treatment of burns, shock, and injuries of specific parts of the body. Anesthesia, plastic surgery, and the psychoneuroses of war will be some of the other topics. Problems of civilian medical care in wartime which will be discussed will include the responsibilities of individual doctors and hospitals; personnel problems of hospitals; organization of emergency medical services; maintaining adequate supplies, furnishings, and equipment; maintenance of high standards of medical and nursing education and of hospital service in general; hospital public relations; and administrative adjustments in professional staffs of hospitals. The opening meeting of each session will be devoted to discussion of "Medical and Surgical Aspects of Chemical Warfare," led by a representative of the United States Office of Civilian Defense, and the closing meeting, a panel discussion on problems in wartime civilian medical practice, will be led by representatives of the United States Public Health Service, the American College of Physicians, the American Medical Association, medical services in industry, and the American College of Surgeons. Some of the topics for consideration at this meeting will be endemic and epidemic diseases, including tropical diseases; medical services in industry; medical and surgical practice; and supplementary postgraduate education for medical officers and civilian doctors.

The schedule for the War Sessions is as follows:

Date	City	States and Provinces	Headquarters
March 1	St. Paul	Minnesota, North Dakota, South Dakota	Lowry Hotel
March 3	Milwaukee	Wisconsin, Illinois	Schroeder Hotel
March 5	Indianapolis	Indiana, Kentucky, Ohio	Claypool Hotel
March 8	Detroit	Michigan	Statler Hotel
March 10	Pittsburgh	Pennsylvania, West Virginia	The William Penn
March 12	Buffalo	New York, Ontario	Statler Hotel
March 15	Boston	Massachusetts, Connecticut, Maine, New Hampshire, Rhode Island, Vermont	Statler Hotel
March 17	Brooklyn	New York City, Delaware, New Jersey	St. George Hotel
March 19	Richmond	Virginia, District of Columbia, Maryland	John Marshall Hotel
March 22	Charlotte	North Carolina, South Carolina	Charlotte Hotel
March 24	Birmingham	Alabama, Florida, Georgia	Tutwiler Hotel
March 26	Memphis	Tennessee, Arkansas, Mississippi	Peabody Hotel
March 29	Houston	Texas, Louisiana	Rice Hotel
April 1	Kansas City	Kansas, Missouri, Oklahoma	President Hotel
April 3	Omaha	Nebraska, Iowa	Fontenelle Hotel
April 6	Denver	Colorado, New Mexico, Wyoming	Cosmopolitan Hotel
April 9	Salt Lake City	Utah, Idaho	Utah Hotel
April 13	Los Angeles	Southern California, Arizona	Biltmore Hotel
April 16	San Francisco	Northern California, Nevada	Fairmont Hotel
April 20	Seattle	Washington, Montana, Oregon, British Columbia	Olympic Hotel

Dr. Irvin Abell, chairman of the Board of Regents of the College, in announcing the War Sessions, said that although participating states and provinces for each meeting have been designated to facilitate arrangements, there will be no geographic restriction on attendance, and those who plan to attend may select the place and time which are most convenient.

The American College of Surgeons canceled its 1942 national meeting and is holding in abeyance plans for a Clinical Congress in 1943, in the meantime offering the regional meeting plan provided by the War Sessions to save the time of the doctors and other personnel, and to minimize transportation difficulties, without unduly sacrificing during wartime the benefits of medical assemblies.

County News

Bronx County

The next meeting of the North Bronx Medical Society will be held at Elmsere Hall, 284 East 170th Street (JERome 6-8570), March 4, 1943, at 8:30 P.M. The following program has been announced:

"Hematometra in a Woman of 60 Following Stilbestrol Treatment," by Dr. Jacob Juskowitz, with discussion by Dr. Henry Krauskopf; "Nephritic Hypertension in a Boy of 14," by Dr. Tobias

directors of Lowville General Hospital. A director and vice-president of the Croghan National Bank since its inception in 1917, he has also been health officer of the town of New Bremen and is the only civil-service-appointed health officer in Lewis County. He was born in Switzerland, of German parentage, on January 31, 1863. He studied in University of Leipsic, and at the age of 19, came to the U.S. and spent three years in Indiana, then returning to New York and entering New York University, from which he graduated in the medical profession in 1887. He then came directly to Lewis County, where he entered practice with the late Dr. W. W. Jameson, for a few years in the village of New Bremen, and in 1891 opened practice in the village of Croghan.—*Lowville Republican*, February 4.

Nassau County

Dr. J. Rembrandt Helfrick is returning to local medical practice after duty with the United States Army, and has announced the reopening of his office at the corner of Central Drive and Main Street, Fort Washington, where he has been located for the past five years.

Dr. Helfrick, who volunteered for service last spring, has been stationed at the hospital at Fort Monmouth, New Jersey, and at Fort Devens, Massachusetts.

Dr. J. P. Hoguet, who was responsible for the medical protection of the tens of millions of visitors to the New York World's Fair in 1939 and 1940, has joined Republic Aviation as medical director of the Farmingdale plant.

Dr. Hoguet took charge of the hospital staff as successor to Dr. F. J. Roemer, who recently resigned.*

New York County

Under the sponsorship of the New York Academy of Medicine, a conference on maternal health and child welfare was held on February 19 at the Hotel Roosevelt in New York City. The conference was part of the celebration that marked the centenary of the publication by Oliver Wendell Holmes of his paper on the contagiousness of puerperal fever.

Speaking at the morning session on the theme "The Family Faces the Future" were Mr. Lawrence K. Frank, chairman of science, National Resources Planning Board; Dr. A. A. Brill, lecturer in neurology and psychiatry, College of Physicians and Surgeons; Mr. Stanley P. Davies, executive director, Community Service Society of New York, and Dr. Frank Fremont-Smith, medical director, Josiah Macy, Jr., Foundation.

Afternoon speakers included Dr. Louis I. Dublin, chief statistician and third vice-president, Metropolitan Life Insurance Company; Dr. Alan F. Guttmacher, associate professor of obstetrics, Johns Hopkins University; and Miss Hazel Corbin, general director, Maternity Center Association, Inc.

A symposium on the theme "Meeting the Problems of Maternity Welfare and Child Health Along Many Fronts" was presented by the following speakers: Miss Alta Dines, Community Service Society; Miss Frances Taussig, Federation for the Support of Jewish Philanthropic Societies; Mrs. Sidonie M. Gruenberg, Child Study Association of America; Mr. D. Kenneth Rose, Planned Parenthood Federation of America; Dr. Thomas Patrick, New York Urban League; Dr. Leona Baumgartner and Dr. Elizabeth Gardiner, New

York City Department of Health; Mrs. Shepard Kreh, Maternity Center Association; and Dr. Herbert B. Wilcox, New York Academy of Medicine.

. . .

The monthly meeting of the county society was held on February 23 at 8 15 P.M. at the New York Academy of Medicine.

Industrial medicine was the general subject of the scientific session, the program for which was: "Odds and Ends of Industrial Medical Practice," by Loyal A. Shoudy, chief of the medical service of Bethlehem Steel Company, Bethlehem, Pennsylvania; "Typical Occupational Disease Hazards in Industry," by May R. Mayers, Department of Industrial Hygiene, New York State Department of Labor; "Preplacement Physical Examination," by Russell C. Kimball, assistant medical director, Consolidated Edison Company.

. . .

Leaders in public health, including Mayor F. H. LaGuardia, attended a luncheon at the Academy of Medicine on January 21 to pay tribute to Dr. John L. Rice, former Commissioner of Health.

The achievements of Dr. Rice during his term as Commissioner were praised by the Mayor. The influence of Dr. Rice's work beyond this city and throughout the United States was described by Dr. C.-E. A. Winslow, professor of public health of Yale University School of Medicine.

Dr. Ernest L. Stebbins, who has succeeded Dr. Rice as Commissioner of Health, described the solid foundations in administration of the program of the Department made by Dr. Rice and on which Dr. Stebbins is building.

. . .

Health Commissioner Ernest L. Stebbins has declared that closing of New York's laundries would produce a health hazard for the City by increasing the danger of infectious diseases.

Discussing the War Petroleum Administration's recent order classing laundries as a "nonessential industry" as far as the use of fuel oil is concerned, Dr. Stebbins said that even if the oil curtailment reduces laundry service by only 40 per cent, there will be a decline in the City's standards of health and cleanliness, as the majority of residents in the metropolitan area depend on laundries.

Onondaga County

Dr. Charles D. Post has been appointed by T. Aaron Levy, president of the Onondaga Health association as chairman of its tuberculosis committee for 1943.

The problems to which the committee is expected to devote special attention will include local means of promoting tuberculosis case-finding and desirable measures for the educational, vocational, and social rehabilitation of tuberculosis patients after their disease has been arrested. A third problem will relate to the importance of suitable control over nonhospitalized tuberculosis patients.

Other members of the committee will be Dr. William E. Ayling, Dr. Eugene W. Bogardus, Miss Ellen L. Buell, R.N., Dr. Edward B. Bukowski, Commissioner H. Burton Doust, Henry M. Files, Albert L. Halbritter, Dr. L. M. Hickernell, Dr. Robert D. Johnson, Arthur E. Jones, Mrs. William A. Mackenzie, J. F. Sabine Meachern, Dr. O. W. H. Mitchell, Alexis N. Muench, Richard H. Pass,

of the honored guest, presented Dr. Hagedorn with a bouquet of 50 carnations, after which he turned the meeting over to Dr. George Lenz, who acting as toastmaster, presented Dr. Hagedorn with a scroll on which were inscribed the names of each member of his class at Albany Medical School. Dr. Hagedorn was graduated from Albany Medical School in 1892, and of the 54 classmates who graduated with him, all but 15 have passed on.

After the presentation Dr. Hagedorn responded with a talk in which he went back over the first years he practiced the profession. He told of the dirt streets in Johnstown and Gloversville and of the struggles doctors of that time had to reach their patients in winter, often driving miles through snow and cold in a horse-drawn sleigh.

Following the speaking program a short business session was held, during which the following officers were elected: Dr. A. R. Wilsey, president; Dr. Dominic Battaglia, vice-president; Dr. L. Tremante, secretary; Dr. A. H. Sarno, treasurer-board of censors, Dr. W. Shaw, Dr. F. G. Calder, and Dr. B. G. McKillip; Dr. S. C. Clemans, delegate to the State Convention; Dr. B. A. Winne, alternate delegate to the State Convention.*

Herkimer County

The February meeting of the county society took place on February 9 in the Herkimer County Historical Society building.

Dr. Robert Ainslie, of Ilion, spoke on medical work in China. A movie on "Peptic Ulcer" was shown.*

Kings County

The Medical Society of the County of Kings and the Academy of Medicine of Brooklyn held a stated meeting on February 16 at 8:45 P.M. in the McNaughton Auditorium.

The scientific program featured three addresses: "Experiences Aboard the U.S.S. *Vincennes*," by Lt. Com. Samuel A. Isquith, U.S.N., Brooklyn; "Can the Doctor's Bill Be Insured?" by Mr. Wendell A. Millman, associate actuary, Equitable Life Assurance Society of the United States, New York City; and "Nonprofit Medical Expense Insurance," by Mr. Louis H. Pink, president, Associated Hospital Service of New York, Inc., New York City.

There was also the presentation of a medal and scroll to Dr. William C. Meagher, president of the county society and the Academy of Medicine of Brooklyn for the year 1942

"War nerves" is the latest detail in military medicine to be studied at the Long Island College of Medicine in preparation for active service with the armed forces, according to college authorities.

Merchant seamen who have suffered torpedoing and exposure on rafts or in open boats have become a major source of information on "war nerves" for physicians. These cases are studied in hospitals, clinics, and rest centers affiliated with the medical school.

Dr. Howard W. Potter, clinical professor of neurology and psychiatry at the college, who is also medical supervisor of the Port of New York area for the War Shipping Administration and United Seamen's Service, Inc., has been arranging for the students to give special study to these cases.

Military medicine is stressed at the college, with at least one phase of it taught in every department.

All but 15 of the 374 male students hold commissions in the various services.

In addition to the study of "war nerves" the study of burns, shock, traumatic injuries, infections, fatigue, venereal diseases, war gases, and frostbite as applied in military medicine receive special emphasis. Military psychiatry is stressed because of the greater demands which warfare is making on the soldier today.*

The appointment of Dr. Duncan W. Clark, of the department of medicine of Long Island College of Medicine, Brooklyn, as assistant dean of the college has been announced. He succeeds Alfred R. Crawford, who has been named assistant to the president, Dr. Jean A. Curran.

We reprint in full below the account of the organization of the "Committee on Psychosomatic Medicine," which appeared in the February issue of the *Bulletin* of the Medical Society of the County of Kings:

In recent years, contributions in the field of psychosomatic medicine have become potent weapons in the therapeutic armamentarium of the practicing physician.

The New York Hospital, Mount Sinai Hospital, the Presbyterian Hospital, and others in Manhattan have as an integral part of their organizations a group of men trained in psychiatry. This results from the pressure of the reported 35 per cent (most conservative estimate) to the more likely 70 per cent of all hospital admissions who have been shown to suffer from psychosomatic disease. The enlightened clinician will recognize the subtlety with which an emotional upheaval may be expressed by nervous stomach, pain around the heart, cardiac arrhythmias, colitis, menstrual disorders etc. Without psychosomatic therapy the patient will not get well.

In order to get started, a committee was organized under the auspices of the Kings County Medical Society known as "The Committee on Psychosomatic Medicine." The purposes of the committee are:

- 1 To teach the doctors of our society these more recent therapeutic concepts
- 2 To establish in our hospitals personnel trained in psychosomatic psychiatry who will be available for therapy and research.

The committee consists of a chairman who is an internist with psychoanalytic training, two psychiatrists, a cardiologist, urologist, gastroenterologist, gynecologist, and others will be added as the need arises.

The office of chairman was assigned to Dr. A. J. Nathaniel Rosen, the psychiatrists are Doctors Sands and Potter, the section on obstetrics and gynecology will be handled by Dr. Alfred C. Beck, urology by Dr. Leo Drexler, gastroenterology by Dr. Henry Frederick Kramer, cardiology by Dr. Louis Sigler.

The educational program will be launched with a paper by Dr. Lawrence S. Kubie on April 2, 1943, as one of the regular Friday afternoon lecture series. His subject matter will consist of physiological mechanisms by which psychosomatic illness expresses itself.

Lewis County

Dr. Paul H. Von Zierolshofen, more familiarly known as "Dr. Paul," quietly observed his eightieth birthday, at his home in Shady Avenue in Croghan, where he has resided the past fifty years.

He is believed to be the oldest practicing physician in Lewis County and is still kept busy attending numerous patients in his office daily. He is enjoying fairly good health. He is a member of the Lewis County Medical Society, of which he was formerly president, and he is still a consultant on the staff of the St. Lawrence State Hospital, Ogdensburg. He is also a member of medical board of

Hospital News

Largest Army Hospital Opened

OPERATED for several months in complete secrecy, the Halloran General Hospital on Staten Island was recently revealed by the Army to be its largest hospital, intended for treatment of soldiers wounded in Europe, Africa, and the South Pacific.

The new development, composed of one large, seven-story medical and surgical building, and several smaller buildings for wards, mess halls, garages,

greenhouses, auditorium, and recreational facilities, was originally planned as an institution for mental defectives and was taken over by the Army from the New York State Department of Mental Hygiene.

The hospital is named for Col. Paul S. Halloran, who was long connected with the Army Medical Corps. Director of the hospital is Col. Ralph G. DeVoe, who is assisted by Major George Vassos, formerly a surgeon at Bellevue Hospital.

Bachelor of Medicine for Nurses Suggested

THERE is a growing need for an expansion in the training of nurses, according to Dr. Hugh Cabot, writing in *The Modern Hospital* for February. Dr. Cabot believes that the nurse's field should extend beyond the scope of mere hospital care and should give her an opportunity to do work in preventive medicine and positive health technic.

"I have long believed," Dr. Cabot writes, "that women are better suited than men to studying environment, giving appropriate advice, and feeling their way along deftly in complicated and varying conditions of environment. All these things used to be done in a simpler world by the general physician, but...our knowledge in all the fields broadly covered by the phrase 'preventive medicine' has increased to such an extent that, with proper and detailed supervision, much disease can be permanently avoided and many... [unwholesome] condi-

tions... which undermine health... can be headed off and replaced by positive health. However, these things cannot be done by the personnel now available."

Dr. Cabot goes on to say that women trained in this work would be "more involved in what is properly known as the practice of medicine than are the trained nurses of today. We, in this country, have made little use of the degree, Bachelor of Medicine."

"This would, I believe, be an appropriate indication of their relation to medical service as a whole. It would suggest that they did not have the elaborate scientific training of the physician but, at the same time, would make it abundantly clear that they were involved in the practice of medicine and were essential cogs to anything approaching complete medical care in step with modern science."

At the Helm

Charles S. Andrews has been re-elected president of the Lawrence Hospital in Bronxville.

Other officers re-elected were: Thomas B. Gilchrist, vice-president; J. Robertson MacColl, Jr., secretary; and Frankland F. Stafford, treasurer.*

. . . .

Harold B. Fuller has been re-elected president of the Chenango Memorial Hospital in Norwich.

In addition to President Fuller, directors at their organization meeting named Charles R. Kroeger, first vice-president; Carl E. Fibley, second vice-president; L. Forrest Hotchkiss, treasurer; and W. A. Seely, secretary.*

. . . .

Harrison B. Wright, of Rockville Centre, is the new president of the South Nassau Communities Hospital Association, having been elected by the board of directors to succeed Mrs. Walter R. Hood.*

. . . .

Mrs. George W. Battersby, of Gouverneur, who has been associated with the work at Stephen B. VanDuzee Hospital for some years, has been chosen by the hospital board to become acting superintendent of the institution.

Mrs. Battersby succeeds Miss Mildred Higgs.*

* Asterisk indicates that item is from local newspaper.

The board of trustees of Ossining Hospital have re-elected Walter L. Johnson, of Briarcliff Manor, as chairman of the board, and James H. Carter, of Scarborough, as president of the Association.

Other officers of the Association chosen last night are Wallace T. Miller, vice-president, succeeding Mrs. Walter B. Mahony; John J. Murray, re-elected secretary, Ralph Roberts, re-elected treasurer; and Stanley E. Young and George F. Hoag, re-elected assistant treasurers.*

. . . .

Miss Leoni H. Jackson has been appointed superintendent of nurses of the Long Beach Hospital, succeeding Mrs. Edward Johnson.*

. . . .

Dr. M. J. McGrath has been elected president of the Oswego Hospital staff. Other officers include: Dr. Milton W. Kogan, vice-president; Dr. W. McD. Halsey, secretary; and Dr. D. D. O'Brien, treasurer.*

. . . .

Dr. G. Marcellus Clowe is the newly appointed chairman of the medical board of Ellis Hospital in Schenectady. Dr. Clowe, who will represent the division of medicine, succeeds Dr. Lester Betts, who has served as chairman for the past three years.

Dr. Clowe has been president of the hospital staff for the past year and is senior attendant on the medi-

Dr. Edward J. Wynkoop, and Dean Herman G. Weiskotten. Arthur W. Towne, secretary of the association, is to serve as secretary.

Dr. Post is chairman of the committee on diseases of the chest in the Medical Society of the State of New York.

Announcement also was made by Mr. Levy of the personnel of the association's executive committee, of which he acts as chairman. Those serving on the committee are Dr. Eugene W. Bogardus, Miss Buell, Donald E. Chappell, Thomas J. Corcoran, E. Philip Crowell, Commissioner Doust, Dean Harry S. Ganders, Dr. J. G. Fred Hiss, Dr. Thomas F. Laurie, Mrs. Mackenzie, Mr. Meachem, Dr. Mitchell, Dr. Post, and Dean Weiskotten.*

Orange County

Dr. Anthony J. Manzella, former Newburgh health officer, has been made available for public health service through the procurement and assignment division of State Medical Society and went to Albany on February 1 to work with the State Department of Health.

Dr. Manzella, a native of Buffalo, where he received his medical education in the University of Buffalo, has been in Newburgh since 1933. He was health officer from January, 1938, to October, 1940.

While Newburgh's health officer, Dr. Manzella took a course in public health in Harvard University and secured the degree of Master of Public Health. He will maintain his residence in Newburgh.*

The Medical Expense Fund of New York has issued membership certificates to many Newburgh individuals.

More than half the doctors of Orange County are professional members of the fund and twenty-seven physicians in Newburgh are affiliated with it.*

Richmond County

The regular meeting of the county society was held in the auditorium of the Public Health Building on February 11. In the absence of Dr. H. Lynn Halbert, the chair was held by Dr. D. V. Catalano.

Judge Walsh, as a representative of the Civilian Defense Volunteer Office, spoke, outlining the purpose, functions, and organization of the "block" plan.

Dr. Ethel Leonard, of the Staten Island Hospital, spoke on "Medicine in China." Her talk was based on her own experiences as a general practitioner in Peking for fifteen years.

Schenectady County

The *Schenectady Union Star* of January 21 carried the following announcement:

"A new medical program for clients of the Schenectady County Department of Public Welfare and the Board of Child Welfare will be put in operation on February 1, Leo H. Vosburg, county welfare commissioner, said today. Mr. Vosburg indicated that a central medical unit will be established for the county under the direction of a physician, to be known as medical consultant and to be employed by the county. . . .

"The consultant will be assisted by an advisory committee composed of representatives of the Schenectady County Medical Society, a representative of the dental profession, and a pharmacist. Mr. Vosburg . . . listed the following as members of the advisory committee: physicians—Dr. James M. Blake, Dr. C. F. Rourke, and Dr. Ralph D. Reid; dentist—Dr. George W. Miller; and pharmacist—Walter D. Prybylek.

"The program will apply to all categories of public assistance administered by the county welfare department. Functions of the consultant will include acting as a sort of liaison officer among the Department of Public Welfare, the Board of Child Welfare, town welfare officers, the medical profession, and vendors (druggists).

"The program is described in a medical manual, which includes a long list of reimbursable charges set up by the state. These include specified payments for practically everything from office calls through various kinds of medical attention to the compounding of prescriptions."*

Tompkins County

Dr. Louise C. Mooney has reopened the offices for the practice of internal medicine formerly conducted by Dr. C. Stewart Wallace and Dr. Norman S. Moore in the Seneca Building.

Dr. Mooney came to Ithaca in July after completion of a residency in internal medicine at Cook County Hospital, Chicago. More recently she was a member of the resident staff of the Cornell University Infirmary and Clinic, which position she resigned on January 1 to enter the private practice of internal medicine.*

Deaths of New York State Physicians

Name	Age	Medical School	Date of Death	Residence
Edward Adams	65	Cornell	February 7	Manhattan
James J. Cuono	54	L.I.C. Hosp.	January 28	Brooklyn
Jacob N. Feinberg	52	Univ. & Bell.	February 10	Long Island City
J. Frank Fraser	76	Bellevue	January 31	Manhattan

J. Herbert Irish	72	N.Y. Hom.	February 2	Syracuse
Samuel Kavinoky	67	Buffalo	January 23	Buffalo
Rolfe Kingsley	61	P. & S., N.Y.	February 4	Bronx
Sylvester J. McNamara	73	L.I.C. Hosp.	January 31	Brooklyn
Percy C. Snowden	75	Vermont	February 7	Peekskill
Clarke W. Stewart	70	Niagara	January -	Olean
Walter B. Wellbrock	67	L.I.C. Hosp.	February 3	Lindenhurst

and the medical staff, will be: Drs. W. C. Travis, Joseph G. Patiky, and J. L. Sengstack.

Dr. J. L. Sengstack will be chief of the surgical department, with the following members: Drs. M. R. Keen, urology; W. P. Kortright, Joseph G. Patiky, and W. C. Travis. The following associate surgeons have been elected: Drs. R. M. Arkwright, C. E. Drysdale, William Duesselmann, and Joseph Libert, praxtology.

The department of medicine will include: Dr. Neil E. Falkenburg, chief; Drs. Anthony Firenze, cardiology; and William J. Delaney. The following are associates in medicine: Drs. William L. Bennett, Mathew dePasquale, C. V. Granger, E. Hofmann, and W. Novotny.

In the department of obstetrics are: Drs. Samuel Teich, chief; and L. P. G. Gouley, acting chief. Associates are: Drs. Benedict Kurshan and A. R. Cherry.

Associates in ear, nose, and throat are: Drs. T. W. Faulkner and Max Kimbrig.

On the staff in anesthesia are: Dr. C. Bernstein, chief, and Dr. N. E. Falkenburg, acting chief.

The emeritus staff includes Dr. G. Herbert Carter and Dr. Roger Dexter.

Courtesy staff members are: Drs. F. K. Bernstein, George Fair, A. A. Gallo, Karl Horn, Virginia Lent, Sewall Pastor, Alwyn Rand, C. M. Robin, W. D. Schmit, Nino Tamburello, Julius Tenke, and J. D. Verrilli.

The roentgenologist is Dr. L. P. Van Winkle, and the pathologist is Dr. Gordon Priestman.

In addition there are the following specialists serving as consultants at the hospital: general surgery: Dr. Henry Flack Graham, Dr. Edwin Joseph Grace, Dr. Henry W. Louria, Brooklyn; Dr. George Thomas Pack, and Dr. Edward D. Truesdell, New York City; internal medicine: Drs. Adolph Andersen, Lowell B. Eckerson, Henry M. Moses, Brooklyn; Dr. Sidney P. Schwartz, New York City; neurology and serology: Dr. Leon H. Cornwall, New York City; Dr. Harold Merwarth, Brooklyn; epidemiologist: Dr. Burdge P. MacLean, Huntington; radiation therapist: Dr. Benjamin Feuerstein, Bay Shore; obstetrics and gynecology: Dr. Arthur C. Martin, Hempstead; Drs. Harvey C. Matthews and William C. Meagher, Brooklyn; and Dr. Richard N. Pierson, New York City; orthopaedics: Dr. H. C. Fett, Brooklyn; Dr. Otho C. Hudson, Hempstead; pediatrics: Dr. Minor C. Hill, Oyster Bay.*

The board of directors of Soldiers' and Sailors' Memorial Hospital of Yates County re-elected the following officers for 1943: Charles T. Andrews,

president; M. Francis Corcoran, vice-president; George S. Sheppard, secretary; and Christie B. Briggs, treasurer.*

Alexander C. Nagle, of Scarsdale, was elected president of the board of governors of the White Plains Hospital Association on January 21. Other officers are: C. B. Winslow, first vice-president; A. J. Purdy, second vice-president; Arthur H. Titus, of New Rochelle, third vice-president; Otto C. Jaeger, secretary; and George F. Thomas, treasurer.

By an arrangement with the Norwegian Public Health and Disability Service, Norwegian sailors were treated in the hospital in 1942. By the end of the year this group averaged 35 daily. A total of 306 Norwegian patients entered the hospital during the year, and 207 operations were performed for them.*

Dr. Harry J. Worthing recently completed his fifth year as superintendent of the Pilgrim State Hospital in Brentwood. In December, 1937, Dr. Worthing came to Brentwood from Willard State Hospital, where he had served as superintendent for several years. He succeeded Dr. William J. Tiffany, who became Commissioner of the Department of Mental Hygiene.*

The medical staff of Veterans' Memorial Hospital, Ellenville, elected officers for 1943 at a meeting at the hospital on January 7. Named president was Dr. O. Roberts; vice-president, Dr. M. Akin; secretary, Dr. A. Ruggiero; and treasurer, Dr. A. Augustine.*

Dr. Emanuel Giddings, former medical superintendent at Kings County Hospital, Brooklyn, and at present a colonel in the Army Medical Corps stationed at the Walter Reed Hospital in Washington, has been appointed colonel of the 37th General Hospital, Brooklyn.

Victor Smith was again elected president of the board of managers of Memorial Hospital in Catskill at its annual meeting. Harold Moore, of Windham, was named vice-president, and Wilton O. Edwards was elected secretary.*

Newsy Notes

The New York Times published the following special cable from Caracas, Venezuela, on February 9: "A check for 16,536 bolivares was handed to Minister of Development Eugenio Mendoza this morning by officials of the North American Association for a new infantile paralysis hospital here.

"The money represents the proceeds of the Roosevelt Birthday Ball sponsored by the association."

A booklet pointing out the manner in which staff members and patients can save vital materials, manpower, and time is being distributed at Ellis Hospital in Schenectady.

The booklet, "Save for Victory," was prepared by staff members of the hospital in collaboration with officials of other hospitals in Northeastern New York. It is being distributed also to staff members and patients at hospitals in Albany and Troy.

cal service. He is physician in charge and director of the medical service at Union College, where he is a member of the faculty.

Dr. Albert Grussner was appointed to the medical board, representing the division of surgery. He succeeds Dr. E. MacDonald Stanton, who has served in that capacity for the past three years.

Dr. Grussner, senior surgeon on the hospital staff, also is chairman of the surgical group section of the hospital.

Dr. William M. Mallia was reappointed to the medical board, representing the division of obstetrics and gynecology, and Dr. A. R. Warner was reappointed to represent miscellaneous specialties.*

James R. Clark, superintendent, Southside Hospital, Bay Shore, Long Island, has been appointed to head the War-Time Service Bureau of the A.H.A., which was authorized at the St. Louis convention.

Mr. Clark has been in hospital administrative work since 1928. His education was obtained at Temple University, and he attended the Chicago Institute for Hospital Administrators in 1934.

From 1926 to 1928, Mr. Clark was an efficiency engineer in New York. He then became associated with Jewish Hospital of Brooklyn, first as executive secretary and then as assistant director. He became director of the Southside Hospital in 1935.

Mr. Clark is a member of the A.C.H.A., the A.H.A., the New York State Hospital Association, and the Greater New York Hospital Association. He is a member of the public and medical subcommittee to study hospital standardization of the latter group. He has been secretary-treasurer, membership committee member, and vice-president of the Hospital Council of Brooklyn.

At the seventh annual meeting of the Chautauqua Region Hospital Service Corporation held recently the following officers and directors were re-elected for the ensuing year: Rev. Dr. Alfred E. Randell, president; Dr. John S. Hickman, vice-president; Mrs. Felicia Grace Hall, secretary; Harold C. White, Sr., treasurer; directors: Felicia Grace Hall, Martha T. Grandin, Robert R. Dew, John S. Hickman, Henry K. Leworthy, Alfred E. Randell, Harold C. White, Sr., Fred A. Chindgren, J. Gustaf Sundin, Hugh L. Gillis, and Donald P. Braley.

The American Hospital Association Approval Certificate was presented, indicating that the corporation has met all the standards for nonprofit hospital service established by the Hospital Service Plan Commission, in recognition for the improvement in public welfare, adequate representation of professional and community interests, and active support of participating hospitals.

The following hospitals are connected with the Chautauqua Region Hospital Service Corporation: Woman's Christian Association; Jamestown General, Brooks Memorial, Dunkirk; Westfield Memorial, Westfield; and the Rhinehart Hospital, at Silver Creek.*

Herbert R. Leggett was re-elected president of the Saranac Lake General hospital for a third year at a meeting of the hospital's board of directors.

T. Edward Williams was elected to succeed Mrs. F. Ferris Hewitt as vice-president, and S. M. Fred-

eriksen was elected to succeed M. M. Munn as treasurer. C. S. Barnet was re-elected secretary.

Four new members were appointed to the board of directors. They are Woodward D. Clark, Clifford W. McCormick, Mrs. Irving Altman, and S. M. Frederiksen. Other members of the board are C. M. Palmer, Mrs. Joseph L. Nichols, Mrs. F. Ferris Hewitt, Mrs. Lawrason Brown, T. Edward Williams, Fred C. Conrad, Matthew M. Munn, Dr. E. R. Baldwin, Dr. Hugh Kinghorn, Miss Julia Conklin, Thomas P. Ward, Miss Mary Prescott, Miss Madeline Smith, Miss Celeste Theriot, D. S. McCrum, M. M. Feustmann, Lee Gray, and Mrs. Robert Wainwright.

Mrs. Catherine Collins is superintendent of the General Hospital, and Miss Phyllis Walters is the assistant superintendent.*

Dr. Jack Masur, administrator of Lebanon Hospital, New York City, now serves in the Office of Civilian Defense in Washington, D. C., as a hospital administration specialist. Lionel J. Simmonds, former superintendent of the Hebrew Orphan Asylum in New York, will succeed Dr. Masur as Lebanon Hospital administrator.

Lt. Col. Florence A. Blanchfield has been appointed superintendent of the Army Nurse Corps, effective June 1, to succeed Mrs. Julia O. Flikke, who will retire May 31.*

Dr. Charles F. Mignin, of the Mary Jemison Trail, has been named acting superintendent of Wyoming County Community Hospital, Warsaw, by the board of managers. He succeeds Wayne Copeland, who is on leave while in military service, and will continue in the office until Mr. Copeland returns. Dr. Mignin, a retired physician now engaged in farming, has served as chairman of the board of managers of the hospital for several years.*

Lawrence E. Kresge has been given a leave of absence from his position as superintendent of the Auburn City Hospital, Auburn, New York, to accept a commission in the Army Medical Administrative Corps. Jerome F. Peck, Jr., has been named acting superintendent for the duration.

Newman M. Biller, assistant director of Montefiore Hospital, New York City, has been appointed executive director of the Home for Aged and Infirm Hebrews, New York City. He will be succeeded at Montefiore Hospital by Dr. Sigmund L. Friedman.

Dr. Edward D. Truesdell will continue to serve as medical director of the Huntington Hospital, it was announced following the annual meeting of the board of directors of the hospital. Staff officers elected are: Dr. Morris R. Keen, president; Dr. Wilbur C. Travis, vice-president and treasurer; Dr. Warren P. Kortright, secretary. The joint conference committee, which, with an equal number of members of the board of directors, considers all matters of common concern to the board of directors

uary with the completion of a temporary heating arrangement, according to H. M. Walton, Jr., chairman of the hospital committee.

Almost all outside work on the building has been completed. Shipments of equipment and furniture are being received daily.

Mr. Walton has announced the receipt of two gifts of \$500 to go toward the cost of the new structure. The government will provide \$133,000 to the total cost.

Completion date for the hospital, begun last July 1, has been set for sometime after March 1.*

WINGS FOR THE DOCTOR

Aviation has introduced many new elements into the duties of military physicians. The Air Corps surgeon is as much at home in a plane as he is in an operating room.

In fact, medical officers in all branches of the armed services have taken to the air.

It is not only in their mode of transportation that modern military physicians have become air-minded. The Air Corps medical officer must not only provide medical service for flight and ground crews but must check their food and clothing and even study plane design from the viewpoint of health protection.

This is no matter of stereotyped routine. Aviators' clothing, for example, must be warm enough to protect the body at high-altitude temperatures of 60 degrees below zero and at the same time allow flyers to climb into the cockpit at ground temperatures of as high as 120 degrees. Ordinary dietetic

considerations are enhanced by the strain of air combat, which markedly increases vitamin requirements. Flyers must be guarded against carbon monoxide poisoning; ground crews need protection against the possibly harmful effects of cleaning solvents and spray paints. These are just a few of the day-to-day problems of aviation medicine.

In a field as new as this, there is necessarily a vast amount of research to be done; and flight surgeons are playing the dual part of guinea pig and experimenter. In the former role they go through all of the acrobatics of aerial combat; in the latter, they carefully observe physical and mental reactions.

The results of this wartime research will have far-reaching effects on the development of postwar civil aeronautics. Mankind is taking to the air—and flying doctors are helping to make flight safe.—*J. Med. Soc. Co. N.Y.*

SEVEN DIETARY SUGGESTIONS FOR THE AGED

Seven dietary suggestions for the aged are presented in the *J.A.M.A.* for January 2 by Edward L. Tuohy, M.D., Duluth, Minnesota, in summarization of a special article on the subject, prepared under the auspices of the Association's Council on Foods and Nutrition. Dr. Tuohy says:

"1. Elderly people should start the day with a good breakfast. It should include some substantial protein, and what else depends on body weight and activity. Protein adequacy must be maintained at all ages.

"2. As effort lessens and sedentary life supervenes, weight rise or fall should dictate the proportion of carbohydrate taken, and as much of this as possible should be from whole grain. While bran is objectionable, cracked wheat products are not. Enriching flour may be a good expedient, but the objection to dark breads should be lived down. Potato is the next best starch.

"3. For the obese, vegetables and fruits should act as the 'fillers' and provide appetite and zest for eating by meticulous preparation and serving.

"4. The elderly should eat fat sparingly, even as the middle-aged should use it cautiously. The high cholesterol sources (egg yolk, cream, and animal fats) should probably be curtailed wherever body build, family history, and other indications portend

atherosclerosis. It is the one decisive indication for dietary restriction after full stature has been attained. The danger of high blood cholesterol is not universal.

"5. Tea, coffee, and alcohol are useful stimulants. The abuse of alcohol places it for some people in the category of both refined carbohydrate and animal source fat. As a vasodilator, it inspires as well as flushes the aged. One cannot say as much for tobacco. It soothes and cuts off circulation. The quiet postprandial puff is rapidly becoming a continuous process. Tobacco is safer after 60 than before, because age has by that time made the blood vessels less elastic and labile.

"6. Food and water (hot drink) taken at regular intervals revive the old. Food becomes the best sleep producer, even though early wakefulness follows. Fruit juices add the needed vitamin content.

"7. Hunger lessens as age advances. Foods less calorically (condiments, broths, relishes) have a place. The teeth, gastric acidity, probably absorptive powers, vitamin storage—all begin to fail with age. We are able to compensate for these losses with vitamins, iron, calcium, hydrochloric acid, and a balanced diet. The mouth becomes the nutritional barometer of health."—*A.M.A. New*

Patients are advised to ask for no more nurses than necessary, to share nurses with other patients, to give up special-duty nurses at the first opportunity, to group wants instead of sending for a nurse for single minor attentions, and to reduce both incoming and outgoing telephone calls to an absolute minimum.

Physicians are asked to save the time of nurses, to write orders "clearly and distinctly," not to call on patients during meal hours, to make reservations for patients as far in advance as possible, and to make as large a saving in drugs and supplies as possible.

Hints for nurses include the salvaging of safety pins, conservation of drugs and supplies, care of blankets and other items, and the budgeting of time.

Other conservation and time-saving hints are directed toward the administrative and office staff, housekeepers, laundry, and general employees.

The booklet contains several blank pages on which patients can write suggestions for improving hospital service. Miss Mary G. McPherson, administrator, reports that approximately 51 per cent of the outgoing patients have taken advantage of the blank pages to make suggestions.*

• • •

In order to keep hospital corpsmen of the Navy informed regarding their duties, the Bureau of Medicine and Surgery of the Navy has resumed publication of the *Hospital Corps Quarterly*. The manual was first published in 1917 and was discontinued in 1930. Its purpose is to provide practical and useful information to hospital corpsmen and to assist in orientating them.

• • •

Hard pressed to hold employees tempted by higher pay in other fields, all nonprofit hospitals have been authorized by the War Labor Board to grant wage increases wherever necessary to safeguard the health of communities.*

• • •

The following editorial appeared in the *Utica Observer Dispatch* of February 10:

Improvements

A new children's ward is being added to the Eastern Long Island Hospital in Greenport.*

• • •

Plans are under way for additions to be made to the DeGraff Memorial Hospital in North Tonawanda.*

• • •

Community Hospital in Chatham has just completed a new three-floor wing.*

• • •

Ground work has been begun on a new hospital at Massena.*

• • •

The new wing donated by Edmund A. Guggenheim, in memory of his father, is now in use at Saranac Lake General Hospital.*

• • •

"Hospital Plan, Inc., which began here six years ago today, has had a speedy expansion which indicates it met a widely felt need. Today the plan has more than 95,000 persons enrolled, and had paid out more than one and a quarter million dollars for the care of patients in local and vicinity hospitals.

The local organization, operated without profit to itself and directed by prominent Uticans, was among the pioneers in the country. Now there are 77 Blue Cross plans enrolling 11,000,000 in the nation. The local plan was the first, and one of the few, endorsed by the Farm Security Administration.

"The plan has proved valuable to many patients who have found how useful it can be in time of need. At the same time, hospitals have been guaranteed an income which helps them to keep rates from going higher."*

• • •

The following items concerning Huntington Hospital have been received from W. P. Kortright M.D., Secretary of the Huntington Hospital Association:

"A Doctors' War Fund has been established since October, 1942, and has been maintained by the physicians of the Huntington Township. The purpose of this fund is to provide regular financial assistance (\$100 monthly) to families of those men who have gone into service. In this way it is thought that an adjustment can be made between the civilian income and that of an Army officer. The fund is to be given a one-year trial. Trustees of this fund are Dr. N. E. Falkenberg, Dr. J. G. Patiky, and Dr. W. C. Travis.

"In view of the increased laboratory work done at the hospital, a drive will shortly take place for funds to build a modern, clinical, pathologic laboratory.

"At its annual meeting the board of trustees of the Huntington Hospital confirmed the following appointments for the year 1943: chief of surgery, Dr. J. L. Sengstack; chief of medicine, Dr. N. E. Falkenberg; chief of obstetrics, Dr. S. Teich (in service); acting chief of obstetrics, Dr. L. P. G. Gouley; medical director, Dr. E. D. Truesdell.

"The following staff officers were elected: president of the medical board, Dr. M. R. Keen; vice-president and treasurer, Dr. W. C. Travis; secretary, Dr. W. P. Kortright."

A new, small-sized interval timer has been developed for timing x-ray films in process and for other laboratory work. It can also be used in photographic darkrooms.

The timer is wound, set, and started by turning the pointer to the figure three and from there either forward or backward to the desired number. Any interval from one to fifteen minutes can be timed. At the expiration of the interval a note is struck on the gong. The accuracy of timing is within plus or minus 5 per cent.

White figures on a black background facilitate darkroom visibility. Below the five-minute marking the dial is graduated in half-minute intervals. The timer is housed in an attractive black plastic case.

Interior construction on the new \$200,000 Town of Sidney hospital was begun the last week in Jan-

DIAGNOSIS...Cholecystitis TREATMENT...SORPARIN

Chmcians are continuing to find that a diagnosis of chronic cholecystitis indicates the use of the new botanical agent, Sorparin (Ext. *Sorbus aucuparia* "McNeil")

NONTOXIC

In addition to its value as an hepato-biliary stimulant, Sorparin is nontoxic. There are no known contraindications to its use, not even common duct obstruction with jaundice. Therefore it can be used with safety in jaundice cases.

Sorparin is orally administered in three-grain tablets.

INDICA- TIONS

Chronic
cholecystitis,
hepatic in-
sufficiency,
catarrhal
jaundice

PHYSIOLOGIC ANTISEPSIS WITH **ARGYROL**

NO CILIARY INJURY

DECONGESTION WITHOUT VASOCONSTRICTION

DETERGENT AND DEMULCENT

NO PULMONARY COMPLICATIONS

NO SYSTEMIC TOXICITY

Safe and Effective Mucous Membrane Therapy

The ability to kill micro-organisms is but one of many factors which determine the clinical efficacy of a mucous membrane antiseptic.

It is because ARGYROL impedes bacterial life without injuring the tissues; because it aids and does not impede those natural defensive processes which the tissues employ to throw off infection, and because it is non-noxious to the organism as a whole, that ARGYROL is truly a "physiologic mucous membrane antiseptic."

ARGYROL effects a decongestion through circulatory stimulation and without resorting to powerful artificial vasoconstriction. Because of its unique physical properties it is detergent,

demulcent, and inflammation-dispelling. But it is non-injurious to the cilia—whose vital role in overcoming upper respiratory infections has been repeatedly pointed out. ARGYROL remains equally bland and non-irritating to the tissues in all concentrations from 1% to 50%, and it is free from the dangers of systemic toxicity and pulmonary complications.

ARGYROL has a superior clinical record to all other mild silver proteins and it is chemically and physically different—in colloidal dispersion, in Brownian movement, in pH and pAg and in chemical reactions. Insist on the Original ARGYROL Package.

A. C. BARNES COMPANY, NEW BRUNSWICK, N. J.

ANTISEPTIC EFFICIENCY PLUS

1. SOOTHING AND INFLAMMATION-DISPELLING PROPERTIES
2. NO CILIARY INJURY—NO TISSUE IRRITATION
3. NO SYSTEMIC TOXICITY
4. NO PULMONARY COMPLICATIONS
5. DECONGESTION WITHOUT VASOCONSTRICTION

SPECIFY THE ORIGINAL ARGYROL PACKAGE

The anxiousness of the novice to jump into deep water might well be somewhat curbed by a full reading of *Life on the Mississippi*. The "old salt," too, would be amused by a rereading of Mark Twain's homely philosophy and native humor.—*The Bulletin, Onondaga County*

SAVE TIME-SAVE LABOR

in URINE-SUGAR TESTING with

CLINITEST

1
5 drops urine

3
Drop in tablet

2
10 drops water

4
*Allow for reaction,

Medical Legislation

The following bulletin (No. 3) was issued on February 5 by the Legislative Bureau of the Medical Society of the State of New York.

State Legislation

SINCE the last bulletin the Legislature has been asked to consider a request for the payment by the State of the travel expenses of the psychiatrist-employee when the latter is called to examine a defendant in a criminal action; and it is also asked to consider the proposition that the employer, by furnishing medical services or appliances for replacement or repair of artificial members of the body, shall not by such action be admitting liability for payment of compensation.

Senator Erway wishes the serologic test and the three-day waiting period, applicable to marriage licenses, waived when one of the parties is in the United States armed forces.

Senator Hampton has asked that children under sixteen should not be employed in theatrical performances, motion pictures, or radio broadcast performances without the written consent of the education board.

Senator Coughlin would extend the unemployment insurance provisions to include persons handling food in hospitals and educational and religious institutions.

Assemblyman Devany would license as an undertaker, without further examination, any honorably discharged soldier, sailor, marine, or nurse in the U.S. forces having not less than ten years' employment under supervision of a licensed undertaker.

Assemblyman Beckinella recommends some changes in the law regarding the licensure of dentists from foreign countries.

Assemblyman Devany asks for an appropriation of \$500,000 to establish a program for physical rehabilitation of veterans.

Assemblyman M. Wilson asks for the creation of a committee to investigate the question of reimbursement to the State for the care, maintenance, and treatment of wards.

Assemblyman Glancy proposes that all students who are inducted into the armed forces while in the final year of their course, but before its completion, shall at the close of the war be granted a diploma, and if it is a professional school, a license as well, without further examination.

Senator W. J. Mahoney sponsors a bill which would authorize the Department of Education to revoke the license of an optometrist convicted of advertising.

Bills Introduced

Senate Int. 357—Williamson, provides that tests required of motor vehicle operators and chauffeurs shall include tests for eyesight and general physical condition, as well as color blindness, all such tests to be required for renewal of licenses. Referred to the Motor Transportation Committee.

Comment: Mr. Williamson introduced this bill toward the close of the session last year but no action was taken upon it.

Senate Int. 515—Young; Assembly Int. 647—Milmo, provides for forwarding to executive officer of State Education Department a copy of all charges against physicians in cases in which subcommittee of Medical Grievance Committee, as well as the Com-

mittee, shall deem a trial necessary. Referred to the Education Committees.

Comment: This amendment was introduced at the request of the Department of Education and has the full approval of the Grievance Committee as well as the Administrative Committee of the Board of Regents. It will aid the Grievance Committee in its study of charges by permitting subcommittees to hear the cases first.

Senate Int. 522—Anderson; Assembly Int. 643—Knauf, makes it a misdemeanor to include in any newspaper, radio, display sign or other advertisement, any statement which misrepresents material frames, or mounting or price of lenses or complete eyeglasses, or price of any frame unless advertised with words "without lenses," or which misrepresents service or credit terms. Referred to the Codes Committees.

Senate Int. 528—Baum, prohibits employment of domestic workers in a private household for handling of food or care of children, who suffer from tuberculosis, venereal, or other infectious diseases; householder must require domestic to produce a physician's certificate of good health. Referred to the Health Committee.

Comment: Senator Baum, the new chairman of the Health Committee, appreciates the fact that this is probably not the wisest time to sponsor a bill of this kind, but feels that there is a real need for such legislation and is introducing the bill for educational purposes. He hopes that from the discussion of the bill he may arouse interest in what he rightly considers a serious matter, especially where an infected person comes in contact with growing children.

Senate Int. 557—W. J. Mahoney, requires Education Department to issue a certificate as certified optician to any person meeting specified qualifications; prior to January 1, 1944, examination by optometry board is not required if applicant was engaged in vocation of optician in this State for at least five years prior thereto; certificate entitles holder to make and dispense lenses, spectacles, and eyeglasses on prescriptions of physicians or optometrists; \$10,000 is appropriated. Referred to the Education Committee.

Assembly Int. 427—Younglove, providing for appointment of assistant town physician under certain conditions. Referred to the Internal Affairs Committee.

Comment: Same as *Senate Int. 301—Young*, reported in Bulletin No. 2.

Assembly Int. 544—Breed, provides that crime of sexual intercourse with person in U.S. military service by one infected with venereal disease shall be punishable by imprisonment for not less than 1½ years nor more than 3 years. Referred to the Health Committee.

Comment: In an address given at the annual American Social Hygiene celebration recently, it was brought out that the prostitute is not the principal carrier of infection so far as the military forces are concerned. Investigation has shown that four times as many soldiers are infected from

(Continued on page 468)

Personalized G-E Field Service Is Not Only For The Duration

● To users of G-E x-ray and electromedical apparatus, the maintenance service rendered by factory-trained men in G-E's local branches and regional service depots is increasingly important these days. And they are getting it despite many of the handicaps which war restrictions impose.

For many years this personalized field service has been available to G-E customers everywhere, who have come to recognize it as a prime requisite to the continued satisfactory operation of all high-grade technical equipment. That's why G-E Field Service functioned before the war and will continue, on a still larger scale, in the peace years to come.

Perhaps you've heard about "P.I. and A"—G-E's *Periodic Inspection and Adjustment Service*—which, incidentally, was not inspired by the exigencies of war, but for thirteen years has helped physicians, hospitals, and clinics to keep their x-ray and electromedical apparatus in tip-top operating condition.

To become better acquainted with these service facilities provided for your immediate vicinity, you need only to get in touch with one of the following G-E headquarters offices or regional service depots. You'll find the G-E representative who calls on you a reliable source of helpful suggestions.

In your particular area this maintenance technical service is extended through the following G-E offices and regional service depots

contacts with willing girls in the "teens" as from prostitutes. This bill amends the law by stating the penalty to be imposed for its violation.

Assembly Int. 636—Fogarty, provides that an employee mentally disabled as result of accident arising out of employment shall be entitled to receive medical care and maintenance in public hospital or institution at expense of employer and without deductions from workmen's compensation award. Referred to the Labor Committee.

Assembly Int. 666—Mitchell, empowers New York City magistrate to try to punish any person charged with violating sections of sanitary code, the penalty to be a fine not exceeding \$25, or imprisonment not exceeding 10 days, or both. Referred to the Judiciary Committee.

Assembly Int. 669—Sutor, provides that in case of death occurring without medical attention, coroner may be notified, as well as local health officer, to investigate and certify as to cause of death; legalizes acts heretofore performed by coroners. Referred to the Health Committee.

Comment: This bill passed both houses last year but was vetoed by the Governor.

Assembly Int. 672—Pillion, extends until July 1,

1944, provisions permitting person inducted into military service and licensed to practice medicine, dentistry, and other professions and occupations to apply for renewal of license without examination within three months after termination of military service. Referred to Education Committee.

Comment: Last year Senator Burney and Assemblyman Pillion sponsored a bill which would protect the licenses and registrations of professional people who were inducted into the Army for a period after the close of the war. That bill was enacted into law. Its provisions take care of all who are inducted prior to July 1, 1943. This measure extends the time to July 1, 1944.

PAMPHLET ON VENEREAL DISEASE

A sixteen-page pamphlet entitled "Office Procedures in the Laboratory Diagnosis of Venereal Diseases" is being offered free to all physicians by the Bureau of Social Hygiene of the New York City Department of Health, 125 Worth Street, New York City. A request on a postcard will bring you a copy. The booklet explains approved methods of clinical

pathologic laboratory procedures, all of which may be employed by the practitioner in his own office. These include preparations of gonococcal smears, method of staining, collection of culture material, also detailed data on examination for trichomonas vaginalis, syphilis, granuloma inguinale, lymphogranuloma inguinale, and chancroid.

HITLER AND THE DEVIL

Hitler called the Devil up on the telephone one day. The girl at Central listened to all they had to say. "Hello," she heard Hitler say, "Is Old Man Satan Home?"

Just tell him it's the dictator who wants him on the phone."

The Devil said, "Howdy," and Hitler, "How are you?"

I'm running a hell here on earth, so tell me what to do."

"What can I do," the Devil said, "dear old pal of mine?"

It seems you don't need any help—you're doing mighty fine."

"Yes, I was doing very good until awhile ago, When a man named Uncle Sam wired me to go slow: He said to me, 'Dear Hitler, we don't want to be unkind.

But you have raised hell enough, so you'd better change your mind.'

I thought the lend-lease bill was bluff, and could never get it through,

But he soon put me on the spot when he showed me what he'd do.

Now that's why I called you, Satan—I need advice from you,

For I know that you will tell me just what I ought to do."

"My dear Hitler, there is not much left to tell, For Uncle Sam will make it hotter than I can here in Hell.

I have been a mean old Devil, but not half so mean as you,

So the minute that you get here the job is yours to do.

"I'll be ready for you coming, and I'll keep the fires all bright,

And I'll have your room all ready when Sam begins to fight,

For I see your days are numbered and there's nothing left to tell,

So hang up your phone, get your hat, and meet me here in Hell."

REVIEWED

Ophthalmology and Otolaryngology. Prepared and Edited by the Subcommittees on Ophthalmology and Otolaryngology of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. Octavo of 331 pages, illustrated. Philadelphia, W. B. Saunders Company, 1942. Cloth, \$4.00.

This work is one of a series issued by the National Research Council to present in compact form essential, up-to-date, and reliable information on military surgery.

This manual is a welcome addition to the series and will prove beneficial to any physician who wants it for quick reference or mature study, either in military service or civilian practice. It is designed especially for the general practitioner in order to aid him in getting an inside view of war injuries such as those that may occur in any of the armed forces.

The drawings are excellent for their simplicity so that the beginner may have a clear picture of the subject under discussion.

It is well written and is an ideal companion to texts on ophthalmology and otolaryngology. However, we doubt that anyone would undertake surgery as described herein, unless he has seen these operations performed.

JOSEPH E. BRAUNSTEIN

Practical Survey of Chemistry and Metabolism of the Skin. By Morris Markowitz, M.D. Octavo of 196 pages. Philadelphia, The Blakiston Company, 1942. Cloth, \$3.50.

In his preface the author states: "The material in this book is presented to the students and practitioners of medicine as a general survey of fundamental facts necessary to a better understanding of dermatology." The book is divided into 4 general parts which include: The Chemistry of the Skin, Hematology, Blood Chemistry, and Vitamins in Dermatoses.

It is a difficult task to select for others, or even to attempt to point out for their enjoyment, any one or more of the important items contained in the 29 chapters into which the 4 major parts have been subdivided. Some idea of the contents may be gained through a cursory glance at the headings of the chapters.

The chemistry of the skin deals intimately with the organic and inorganic elements contained within the substance of the skin; biologic oxidation and reduction; the enzymes; the acid-base balance, pigments; and absorptivity and permeability. The chapters on the blood contained in the second part are of vital interest to the general man as well as to the dermatologist. From a dietetic standpoint, the information gained from a chemical examination of the blood may often show the presence of changes that would indicate the proper treatment to pursue. For example, an excess of glycogen, or an increase of uric acid, would indicate a reduced carbohydrate intake and a lowered purine diet, respectively, or an excess of nonprotein or urea nitrogen would call for a decrease in albuminous foods. The subject of vitamins and that of avitaminosis in dermatology are exhaustively treated and represent the latest

thought. The author has written this book to encourage the student as well as the general practitioner to make use of every possible aid which science has placed at his disposal to assist in his diagnosis and treatment. Each subject is treated by the author in such manner as to show the relationship between the facts elicited and their application in practice. A complete bibliography is appended to each chapter.

NATHAN THOMAS BEERS

Management of the Sick Infant and Child. By Langley Porter, M.D., and William E. Carter, M.D. Sixth revised edition. Octavo of 977 pages, illustrated. St. Louis, C. V. Mosby Company, 1942. Cloth, \$11.50.

The sixth edition of this well-accepted single volume, pertaining to the sick infant and child, has the same clarity of purpose as previous editions. New advances, drawn from many sources, have been incorporated.

Particularly excellent is the chapter of 162 pages on "Methods." It is well illustrated and will be found useful to those using the hollow needle and tube.

This book compares favorably with other well-known single volumes on pediatrics.

THURMAN B. GIVAN

Urological Diseases of Pregnancy. By E. Granville Crabtree, M.D. Octavo of 472 pages, illustrated. Boston, Little, Brown and Company, 1942. Cloth, \$6.50.

This volume is a scientific, thorough, and comprehensive work from the able pen of an outstanding urologist.

Dr. Crabtree has had twenty years of active experience in the field and has contributed numerous papers to the literature during that period. He has made a definite effort to establish urologic diseases in pregnancy as an entity. Although the time apparently is not at hand for another subdivision of a specialty, further need for closer collaboration between urologists, obstetricians, and gynecologists is definitely indicated. Even though there are numerous local and constitutional factors peculiar to urology in pregnancy, it must be generally stated that urology is still an entity whether in adults, children, or pregnant women.

The subjects are well illustrated, with convenient references at the end of each chapter. A chapter on toxemia of pregnancy by Dr. George C. Prather is included.

The reader cannot fail to be impressed with the enormous amount of time and effort required by the author to complete the book. He deserves special commendation for his valued contribution, which may be considered as a reference text for urologists, obstetricians, and gynecologists, as well as for the general profession.

Chemotherapy

OF THE PNEUMONIAS

Sulfathiazole exerts a pronounced and rapid bacteriostatic effect upon the most common causative organisms of pneumonia (pneumococci, hemolytic streptococci, staphylococci). It is not necessary to delay treatment of pneumonia until the laboratory report on sputum typing has been received.

In the vast majority of cases Sulfathiazole is administered by mouth; occasionally it is necessary to resort to injection. Only in certain circumstances is specific serum also indicated.

Write for booklet on Sulfathiazole which includes also a discussion on the treatment of gonococcus and staphylococcus infections.

HOW SUPPLIED

Breast Supports

For Pre-Natal and Nursing

Spencer Maternity Support Spencer Nursing Support

Each Spencer Breast Support for pre-natal wear, like *all* Spencer Supports, is *individually designed* for the one patient who is to wear it, to lift and hold breasts in natural, healthful position, without compression.

It improves circulation—protects delicate inner tissues—helps prevent outer skin from stretching and breaking—aids breathing—improves appearance—encourages erect posture. Easily adjustable to increasing development.

Painful, engorged breasts are often relieved by a Spencer, as it allows veins to empty easily. (A further advantage is gained later in increased milk supply from equalization of circulation during pregnancy.)

GUARDS AGAINST CAKING AND ABSCESSING

The Spencer Breast Support for nursing mothers, provides protection against caking and abscessing. Padded slide-fastener in front for nursing convenience.

For service look in telephone book under "Spencer Corsetiere" or write direct to us.

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

[Continued from page 470]

pages, illustrated. New York, Schuman's, 1942 Cloth, \$8.50.

In 1941 Nazi bombs destroyed a good part of the collection of surgical instruments gathered in the course of many years in the building of the Royal College of Surgeons of London. It is, therefore, especially significant to have published at the present time this volume by Dr. C. J. S. Thompson, who is curator of the Royal College of Surgeons and well known as a medical historian, for his book is almost a complete record of the Royal College collections. Dr. Thompson's book is a detailed, comprehensive survey of the development of surgical instruments. Mr. Henry Schuman, the publisher, has presented the work in a beautiful format and deserves credit for his contribution to this significant achievement.

GEORGE ROSEN

Psychological Effects of War on Citizen and Soldier. By R. D. Gillespie, M.D. Octavo of 250 pages. New York, W. W. Norton & Company, 1942. Cloth, \$2.75.

The author of this book has an international reputation as a leader in psychiatry. Here he presents first-hand observations of psychologic effects of modern warfare on the civilian population as well as on the members of the armed forces. He gives an excellent résumé of his experiences in this particular field and makes many valuable suggestions for the prevention of mental disorders. The book is divided into seven chapters devoted to the following topics: changing concepts in psychoneuroses, constitutional factors in psychoneuroses, social factors in psychoneuroses, psychoneuroses among civilians in war, psychoneuroses in the fighting forces, morale—individual, national, and human relationships in the postwar world. There is a bibliography pertaining to articles written by different authorities on special points treated by the author.

This book is a lucid explanation of the modern concepts of the psychoneuroses and naturally is a very timely one.

It is highly recommended to all intelligent people.

IRVING J. SANDS

Central Autonomic Regulations in Health and Disease. With Special Reference to the Hypothalamus. By Heymen R. Miller, M.D. Octavo of 430 pages, illustrated. New York, Grune & Stratton, 1942. Cloth, \$5.50.

There has long been a need for a book on the central autonomic nervous system written from the standpoint of the clinician. The author is essentially a clinician who has combined bedside experience with a sound neuroanatomic and neurophysiologic knowledge of the hypothalamus and its connections. The value of the book lies in the correlation of the central autonomic nervous system in relation to clinical medicine. The author has included terse presentation of cases to illustrate the material. The general practitioner will find a great deal of value in the discussion of the central regulation of respiration, sleep, circulation, water metabolism, the genitourinary system, and the alimentary tract. Chapters on the use of drugs that affect the autonomic nervous system greatly enhance the value of the book.

Furthermore, without having to resort to a textbook on neuroanatomy, the reader will find included

JAMES F. VAVASOUR, M.D.
Physician in Charge

EXECUTIVES ARE ESSENTIAL, TOO!

With manpower the first vital war need, the public and even those that govern activities have narrowed their view of this most important essential to laborers and skilled mechanics—forgetting that executives are equally necessary.

At the Congress on Industrial Health, in January, the program came to a close with a discussion by Dr. Walter Alvarez on "The Care and Feeding of Executives."

Most important was the advice given executives to "slow down," and to take adequate rest and learn to let subordinates shoulder some of the responsibility. Executives, today, are even more essential to their companies and to their country than normally, and we must remember that the mortality of executives and other overburdened brain-workers and the incidence of serious degenerative diseases in this group appear much higher than among manual laborers.

Dr. Alvarez suggested these health rules for executives:

1. Slow down.
2. Take a month's vacation, or at least a short rest now and then.
3. Delegate authority to others.
4. If you cannot sleep, a soporific will be helpful.
5. Do not smoke too much.
6. If you do play, do not play too intensely
7. Don't get angry.
8. If you are gaining weight, avoid fats and sugar.
9. If your heart muscles are not so good, walk and live at a slower pace.

Punctuating this commonsense advice, Dr. Alvarez remarked, "The phenomenon of nervous breakdowns among executives is quite common, probably because such men not only work too long

hours in the office, but also take up most of their time outside with talking shop and making contacts which will apparently be helpful."

Dr. Alvarez characterized an executive as a man who lives intensely and hastily and does strenuously whatever he sets out to do.

He pointed out that the common symptoms of nervous breakdown include a sense of impaired health and energy; getting up tired in the morning; "playing out" by noon; feeling a need for forcing the brain; or feeling a sense of tension. To these can be added, insomnia, increasing irritability, impatience, ill humor, and "a desire to snap heads off."

Another interesting feature of the talk by Dr. Alvarez was his analysis of the overwhelming complexities of modern affairs—science, industry, government—as compared with the comparatively short time given the human organism to adjust itself to them. It is less than a half-dozen generations since life was rather primitive and its demands on the mind very much less severe. In some tropical islands, the inhabitants still live according to their primeval customs. Even in this country, many of our bright youngsters of foreign extraction had grandparents who lived in a routine of simplicity and easy habits. . . .

The brain, therefore, can't take it. "Only a small percentage of men in the nation have the type of keen brain that can grasp the big problems of modern business and science. What is worse, is the fact that even these keen brains are unable to stand for any long time the strain of constant and heavy use."

Nevertheless, concluded Dr. Alvarez, the executive is an important national asset and he must look to his health for the nation's sake.

[Continued from page 472]

a comprehensive description of the anatomy of the hypothalamus and its fiber connections. Contraversal matter has been wisely eliminated.

The material is well organized and interestingly presented. One, therefore, has no hesitancy in recommending this book to the general practitioner as well as to the specialist. Both will feel repaid by securing it for daily reference as well as for the library.

JOSEPH L. ABRAMSON

Medical Manual of Chemical Warfare. Revised Edition. Octavo of 106 pages, illustrated. Brooklyn, Chemical Publishing Company, 1942. Cloth, \$2.50.

This manual begins with a brief summary of chemical warfare agents that may be encountered in a modern gas attack. This is followed by a discussion of the toxic effects produced on the different organ systems by vesicants, pulmonary irritants, and systemic poisons. The nature and effects of the harassing agents are also described.

Methods for decontamination and treatment of casualties resulting from each type of compound are given, as well as the procedures for protecting the body against their toxic action.

An atlas of ten plates showing the various types of lesions that may be encountered is added as an appendix. Much important material has been gathered together to make this book a useful compendium for the medical gas officer.

ALFRED GOERNER

Serology in Syphilis Control: Principles of Sensitivity and Specificity. With an Appendix for Health Officers and Industrial Physicians. By Reuben L. Kahn, M.S. Octavo of 206 pages. Baltimore, Williams & Wilkins Company, 1942. Cloth, \$3.00.

This is not a book of technic. It deals with the principles of serology and represents an amplification of six lectures which were delivered at the U.S. Naval and U.S. Army Medical Schools in Washington, D.C. It is of value to serologists and pathologists who are interested in serologic studies of syphilis. A small book of 191 pages, it has excellent references and statistical diagrams and is a valuable addition to any hospital library. One does not have to agree that the Kahn test for syphilis is the most sensitive and most specific in order to enjoy this book.

M. J. FEIN

Traumatic Surgery of the Jaws. Including First-Aid Treatment. By Kurt H. Thoma, D.M.D. Quarto of 315 pages, illustrated. St. Louis, C. V. Mosby Company, 1942. Cloth, \$6.00.

This well-arranged and intelligently written book is profusely illustrated with photographs, x-rays, and drawings to facilitate the understanding of the text. The text is in clear, easily readable, large type. There are ten chapters, the first three of which are devoted to first aid treatment, examination of the patient, and treatment planning. Chapter IV considers facial and oral war wounds, and Chapter V deals only with traumatic injuries to the teeth.

Fractures and deformities of the mandible, maxilla, condyle, and mandibular joint are discussed, with their detailed treatment, in the main body of the book. The book closes with a chapter which not only elucidates, but also gives examples of diet, bandaging, and nursing care, so essential for recovery in these types of injuries.

EXECUTIVES ARE ESSENTIAL, TOO!

With manpower the first vital war need, the public and even those that govern activities have narrowed their view of this most important essential to laborers and skilled mechanics—forgetting that executives are equally necessary.

At the Congress on Industrial Health, in January, the program came to a close with a discussion by Dr. Walter Alvarez on "The Care and Feeding of Executives."

Most important was the advice given executives to "slow down," and to take adequate rest and learn to let subordinates shoulder some of the responsibility. Executives, today, are even more essential to their companies and to their country than normally, and we must remember that the mortality of executives and other overburdened brain-workers and the incidence of serious degenerative diseases in this group appear much higher than among manual laborers.

Dr. Alvarez suggested these health rules for executives:

1. Slow down.
2. Take a month's vacation, or at least a short rest now and then.
3. Delegate authority to others.
4. If you cannot sleep, a soporific will be helpful.
5. Do not smoke too much.
6. If you do play, do not play too intensely.
7. Don't get angry.
8. If you are gaining weight, avoid fats and sugar.
9. If your heart muscles are not so good, walk and live at a slower pace.

Punctuating this commonsense advice, Dr. Alvarez remarked, "The phenomenon of nervous breakdowns among executives is quite common, probably because such men not only work too long

hours in the office, but also take up most of their time outside with talking shop and making contacts which will apparently be helpful."

Dr. Alvarez characterized an executive as a man who lives intensely and hastily and does strenuously whatever he sets out to do.

He pointed out that the common symptoms of nervous breakdown include a sense of impaired health and energy; getting up tired in the morning; "playing out" by noon; feeling a need for forcing the brain; or feeling a sense of tension. To these can be added, insomnia, increasing irritability, impatience, ill humor, and "a desire to snap heads off."

Another interesting feature of the talk by Dr. Alvarez was his analysis of the overwhelming complexities of modern affairs—science, industry, government—as compared with the comparatively short time given the human organism to adjust itself to them. It is less than a half-dozen generations since life was rather primitive and its demands on the mind very much less severe. In some tropical islands, the inhabitants still live according to their primeval customs. Even in this country, many of our bright youngsters of foreign extraction had grandparents who lived in a routine of simplicity and easy habits . . .

The brain, therefore, can't take it. "Only a small percentage of men in the nation have the type of keen brain that can grasp the big problems of modern business and science. What is worse, is the fact that even these keen brains are unable to stand for any long time the strain of constant and heavy use."

Nevertheless, concluded Dr. Alvarez, the executive is an important national asset and he must look to his health for the nation's sake.

Peter Irving, M.D.
Secretary

[Continued from page 474]

It is the reviewer's honest opinion that this book should be read by every maxillofacial surgeon as well as every oral surgeon. The book demonstrates the necessity for cooperation between these specialists if a good result is to be expected. The one cannot expect proper end results without the aid of the other.

The book is a fine one, thoroughly covering a limited field.

THOMAS B. WOOD

Animals Are My Hobby. By Gertrude Davies Lintz. Octavo of 301 pages, illustrated. New York, Robert M. McBride & Company, 1942. Cloth.

Here is a book about animals written by a woman who combines two rare qualities seldom possessed by one individual—namely, greatness of heart and the ability to express one's thoughts and emotions in a style that makes reading of these pages a joy long to be remembered.

After perusing the book from cover to cover it is difficult to decide whether the author is a thorough scientist, a literary genius, or both. Judging her by the merit of this book, she rightfully belongs to both categories.

To review Mrs. Lintz's book is a labor of love. Here one will find a rather detailed and scientific discussion on modern nutrition. Animal behavior so ably analyzed by the author may profitably be applied to child behavior. In fact, various phases of child care may be borrowed and applied in no small measure from Mrs. Lintz's detailed analyses and from her numerous experiments here cited.

The animals discussed embrace St. Bernards, guinea pigs, reptiles, but monkeys and apes occupy most of Mrs. Lintz's experiments and investigations.

Readers who have enjoyed the work of the late Terhune will find Mrs. Lintz's a postgraduate study. While the former was largely emotion greatly colored, the latter combines with her emotions a goodly quantity of soul and humaneness as well as an enormous quantity of cold scientific information that should prove most valuable as reference material for further study. All through these pages the reader will be conscious of a depth of concern and compassion for God's creatures, big and little, animal and human. To read this book is to come to the realization of the oneness of man and all other living beings, the realization that both are God's children.

HARRY APPEL

Surgical Physiology. By Joseph Nash, M.D. Quarto of 496 pages. Springfield, Charles C. Thomas, 1942. Cloth, \$6.00.

Surgical Physiology is essentially a study of the physiology of the various systems of the body, including the modern physiologic concepts resulting from scientific research.

The title of the book is, we presume, directed toward interesting the surgeon and the student of surgery in a more detailed study of the subject. The subject-matter of this book, however, should be just as important and interesting to the internist as it is to the surgeon, although the chapter on "Surgical Shock" and the section on "Body Fluids" are most important to the surgeon.

The part of Chapter VIII dealing with "Vitamins in Surgery," although brief, is most interesting, as is Chapter XIII, in which the "Physiology of the Thyroid and Parathyroid" are discussed.

The sections dealing with the "Physiology of the Cerebrospinal Nervous System" and the "Autonomic Nervous System" are discussed in detail, giving excellent classifications of various disorders and the physiologic background for degeneration and regeneration as a result of disturbances in these systems.

The physiology discussed in this text is, for the most part, included in various volumes dealing with surgery of the systems of the body, and for this reason the inclusion in one volume of all the important physiology of the body to date makes this text an excellent reference book on this all-important subject.

HERBERT T. WIKLE

Human Pathology. By Howard T. Karsner, M.D. Sixth edition. Quarto of 817 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1942. Cloth, \$10.

This standard textbook, now published in its sixth edition, needs no introduction to the profession. The author has revised the previous text and has added sections referring to current knowledge in order to bring the book up to date. Certain additions to this volume deserve mention; for example, a section on vitamin deficiencies has been included and the question of shock has been studied from the viewpoint of the pathologist. The excellent material on tumors has been enlarged and, as the author states in his preface, has been rewritten to "incorporate the results of recent research." One noticeable feature that distinguishes this from previous editions is the use of more actual photographs of gross and microscopic material, which contrast favorably with many of the old drawings that always appeared to be somewhat artificial. Each chapter of the text is replete with many references bearing on the subject-matter. It is noteworthy that these references cover in many instances the most recent periodical literature. The departure in this edition of the arrangement of the text with shortened lines, provided by the printing of two columns to the page, is a delight to the reader and a credit to the art of the publisher.

THEO. J. CURPHEY

Communicable Diseases. By Nina D. Gage, R.N., and John F. Landon, M.D. Third edition. Octavo of 453 pages, illustrated. Philadelphia, F. A. Davis Company, 1942. Cloth, \$3.50.

This book on the communicable diseases is an excellent text and guide for the nursing profession. In this, the third edition, it has been brought further up to date by the addition of six chapters and twelve illustrations. New chapters have been added on yellow fever, plague, and tetanus, while those on diphtheria, scarlet fever, poliomyelitis, and psittacosis have been revised or rewritten. The book is essentially a practical one with brief, simple clinical descriptions of the respective diseases and with detailed discussion of their nursing care. The authors have been particularly interested in adopting the text to the rapidly changing conditions of professional life. Nurses will find this volume instructive and useful in handling cases of communicable diseases.

THE PHYSICIANS' HOME

Our part in this most critical period of our Nation's history is not on the battle front, but here on the home front.

Our job, in this insecure world, is to meet the needs of aged and worthy colleagues of our profession. In these trying times it is a responsibility which symbolizes a way of life among professional people.

The Physicians' Home has won the confidence of the Physicians of the State of New York. It must continue to serve.

Join with us in bringing comfort, security and happiness in 1943.

Make checks to PHYSICIANS' HOME,
52 E. 66th St., New York City

[Continued from page 477]

U.S. Army, Robert H. Ivy, Chairman. Octavo of 432 pages, illustrated. Philadelphia, W. B. Saunders Company, 1942. Cloth, \$5.00.

The first chapter of this manual deals with general considerations. It stresses the restoration of function as well as the cosmetic result, and it demonstrates the essentials which must be worked out together with the undesirable procedures which must be avoided in order to attain a successful end.

Chapter Two consists of condensed discussions on the subjects of "Free Mucous Membrane," "Face Including Bone," "Infections of the Mouth and Neck"—all of which are deeply instructive and a refreshing departure from the usual form used by many authors.

Cheiloplasty, the reconstructive surgery of the lips and mouth; meloplasty, the plastic surgery of the cheek; blepharoplasty, that of the eyes and lids; otoplasty, that of the ears; rhinoplasty, that of the nose; cervicoplasty, that of the scalp and cranium; and loss of the hard palate—each is dignified by a complete chapter. Nothing essential has been omitted.

Fractures of the jaw alone take up 54 pages and show the beautiful results that can be accomplished when the dentist and the surgeon cooperate.

The last two chapters of the book are given to the important consideration of general and local anesthesia, so vital to the success of maxillofacial and plastic surgical procedures.

The outstanding facts that impress the reviewer are the strict avoidance of debatable points and useless verbiage, as well as inclusion of past mistakes of some other authors on this subject. Although the book is officially approved for use by the medical departments of the Army and Navy, the doctor in civil practice will also find it of decided value because it represents the present modern approved and accepted methods in maxillofacial procedure. It is both textbook and reference work combined in one—a fine work.

THOMAS B. WOOD

Problems of Ageing. Biological and Medical Aspects. Second edition. Edited by E. V. Cowdry. Octavo of 936 pages, illustrated. Baltimore, Williams & Wilkins Company, 1942. Cloth, \$10.

This is more than just a book covering the diseases of old people, for it is a discussion by many authors of the different aspects of the ageing process. Chapters deal with the ageing of plants, protozoa, insects, and vertebrates, as well as with disorders of the various systems of the human body.

It is emphasized in the foreword that the "problem of ageing is not a purely biological question, but has large cultural, social, and psychological implications." Indeed two of the most interesting and unusual chapters discuss the psychologic aspects of ageing (Miles) and psychologic guidance for older persons (Lawton). The latter author believes that for older people as well as younger ones, psychologic guidance rests on the conviction that it is possible to convert faulty adjustments into more efficient ones. The chapter deals with means of recognition and correction along these lines.

Other chapters of special interest are those on the point of view of the clinician, by L. F. Barker, and one called "Down through the Ages," by C. M. McKay, which is composed of quotations taken from the literature of the past and dealing with old people.

Some patients prefer cream

Ortho-Creme is a soft, white, pleasantly-scented cream, designed for those patients who prefer a cream type base to a jelly. Inasmuch as the acceptability of the method depends largely upon the esthetic qualities of the product, many physicians offer their patients a choice between cream and jelly. Ortho-Creme is active chemically, and tolerable to the vaginal mucosa. You can prescribe it with confidence. Available in plain and printed packages.

Give the cigarette they prefer to get*

IT'S EASY to understand why cigarettes are the preferred gift in the armed services. But did you know that among them the best-liked brand* of cigarette is Camel? Camel is the popular choice of millions and millions of smokers for its finer flavor and superior mildness.

Send Camels, the service man's favorite, to the friends or relatives who are fighting our battle—fighting them efficiently and unselfishly. Your thoughtfulness will be appreciated.

Tobacco stores feature Camels by the carton. See or telephone your dealer today.

Remember, you can still send Camels to Army personnel in the U.S., and to men in the Navy, Marines, or Coast Guard wherever they are. The Post Office rule against mailing packages applies only to those sent to the overseas Army.

* With men in the Army, the Navy, the Marine Corps, and the Coast Guard, the favorite cigarette is Camel. (Based on actual sales records in Post Exchanges and Canteens.)

POLLEN ANTIGENS

Lederle

FOR COUNTLESS CENTURIES the sign of Aries (the ram) has ushered in the season of growing plants—warning of the inevitable pollen season in the months to follow.

No satisfactory cure for Hay Fever has yet been discovered, but it can often be prevented or alleviated by Pollen Antigen immunization in advance of the season.

"Pollen Antigens *Lederle*" are glycerinated extracts possessing adequate stability, prepared and standardized with great care in our laboratories. Their use during recent years, in all sections of the United States has given satisfactory relief in many thousands of cases.

Lederle literature on the various pollen antigens of the United States may help you solve some of your troublesome cases.

Help for the HARASSED

HEART in HYPERTENSION

MYOCARDITIS and ANGINA PECTORIS

with DIURBITAL

DIURBITAL* helps two ways to relieve the hypertensive heart burdened by vascular disturbance and excessive fluid. DIURBITAL acts to relieve edemic pressure by prompt and efficient diuretic benefits . . . it serves to improve coronary blood flow for better cardiac tone and nutrition.

VASODILATOR, DIURETIC, SEDATIVE and CARDIOTONIC, DIURBITAL affords excellent xanthine effects in gradual and sustained REDUCTION OF ELEVATED BLOOD PRESSURE. Apprehension, dizziness, insomnia and other hypertension syndromes are usually well controlled. . . . No gastric disturbance as DIURBITAL tablets are enteric coated. Prompt and maximum utilization.

Each DIURBITAL Tablet contains the soluble double salt Theobromine Sodium Salicylate, 3 grs.; Phenobarbital, 1/2 gr.; Calcium Lactate, 1 1/2 grs. Bottles of 25 and 100 tablets at all pharmacies.

Effectiveness plus Palatability in GASTRIC ULCER MEDICATION

ALUMINOID supplies the time-tested therapeutic value of aluminum hydroxide and eliminates any possible objection to the taste of gels on the part of the patient. Aluminoid affords relief by hydrogen ion adsorption rather than by chemical neutralization. After-acid tides are avoided.

Aluminoid is available, in easy to swallow gelatin capsules, through the better prescription pharmacies. Literature and samples will be sent to doctors on request.

The doctor* oughta know about this..

WITH an empty Karo bottle, a baby has a right to complain. A perhaps, Doctor, so have you. We admit that occasionally grocers do not have Karo syrup.

The situation is this: The great demand for Karo by the armed forces and a huge increase in domestic needs so far exceed our capacity that we are not always able to keep all grocers supplied.

We cannot step up quantity any further without letting down on quality; for this we will *never* do.

If any patient complains that she is unable to obtain Karo for her baby, please tell her to write us direct, giving us the name and address of her grocer and we will promptly take steps to provide this grocer with Karo.

CORN PRODUCTS REFINING COMPANY
17 Battery Place, New York, N. Y.

* INCIDENTALLY, Doctor, Red Label Karo and Blue Label Karo are interchangeable in standard feeding formulas. Their chemical composition is practically identical, their caloric values are equivalent. So if your patients cannot get the flavor you prescribe, please suggest that either Blue or Red Label may be used.

In Nasal Congestion

CHECK OUR FINDINGS

- ✓ 1. More potent vasoconstriction.
- ✓ 2. Immediate action.
- ✓ 3. Decongestion for 2 to 6 hours.
- ✓ 4. Correct pH value.
- ✓ 5. No retardation of ciliary activity.
- ✓ 6. No damage to nasal mucosa.
- ✓ 7. No compensatory swelling or local irritation.

Years of extensive laboratory and clinical research have established **PRIVINE* Hydrochloride's** efficacy as the most modern and powerful synthetic vasoconstrictor now available to medical practice.

*Trade Mark Reg. U.S. Pat. Off.

CIBA

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

IN nasal congestion due to Colds, Hay Fever, Rhinitis, Ethmoiditis and Rhino-sinusitis *PRIVINE Hydrochloride* quickly clears the nasal pathways. Its markedly prolonged duration of effect is outstanding . . . in most cases the vasoconstriction lasts from two to six hours.

Great care has been exercised in preparing *PRIVINE Hydrochloride* solutions to meet all requirements for modern nasal medication.¹ The isotonic and

buffered solution restores the normal pH of the nasal mucosa and maintains ciliary activity.

PRIVINE Hydrochloride (Brand of Naphazoline) applied either by drops or nasal spray is preferred by physician and patient due to its lack of local or systemic side effects. Available in 0.1% solution in 1 oz. bottles and also 0.05% in 1 oz. bottles for children. Literature and samples on request.

PHARMACEUTICAL CHEMISTS SINCE 1852

A Sign of Strength . . . *to endure through changing times*

Consider the situation: Millions of women engaged in the heavier work of industrial jobs. Domestic help growing scarce so that even housewives work harder, longer. More maternity patients than in any time during the last two decades.

Result: More and more physicians are recommending Camp Scientific Supports according to the needs of the particular condition.

Easy to see why the symbol of Camp service is today more important than ever.

It assures doctors that every prescription for a Camp support will be filled exactly as ordered . . . by an expert, specially trained by the Camp organization.

It means that patients will find the prescribed garment available for immediate use, and at moderate prices.

Today, this responsible Camp service is a bulwark for physicians. For in an increasingly unstable field, it is filling a growing need unfailingly.

LIQUID TABLETS CAPSULES

The Ages of Woman

Estrogenic Substance—

An oil solution of all the naturally occurring estrogens, principally estrone and estradiol, for intramuscular injection. Supplied in ampuls and rubber-capped vials of 2000, 5000, and 10000 I. U. per cc.

Not seven, but four, are the ages of woman which call for aid against a lack of secreted estrogen: (1) in childhood if there is gonorrheal vaginitis; (2) in old age if there is vaginitis or vulval pruritus; (3) following parturition to suppress lactation; and (4) numerically most important, in symptoms of the menopause.

Individualized dosage with emphasis on small amounts has minimized toxicity and multiplied patients who may be benefitted by

Diethylstilbestrol-Breon

Early recognition of the need in menopausal disturbances of small dosage led Breon to provide tablets of 0.2 mg. When greater dosage is needed and is practicable, as during the puerperium, larger dosage is available. Forms and strengths of Diethylstilbestrol-Breon are:

For oral use:

tablets of 0.2 mg., 0.5 mg., and 1 mg.

For intramuscular injection:

1 cc ampuls of 0.5 mg. and 1 mg.

For vaginal application:

suppositories of 0.5 mg.

NEW YORK—SAN FRANCISCO

An extra instrument for your over-burdened hands

If one out of every three physicians is called to the colors the men remaining in civilian practice face the profession's most heroic task.

Now, as never before, physicians are entitled to every available aid. Nature created such an adjuvant in the carbonated mineral waters of Saratoga Spa. Around them, under New York State guardianship, facilities were organized for your use.

Many physicians have long recognized the established therapeutic values of the waters in treating conditions where ex-

ternal or internal use of them is indicated. Many physicians realizing that breakdowns in general health follow the heavy strains and pressures of these times, prescribe a stay at the Spa.

Relaxation found in the restful environment of Saratoga brings that relief from tensions which prepares your patients for the full benefit of your continuing medical direction. The Spa Medical Staff does not practice; it only oversees treatments prescribed by you or the local specialist you choose for your patient's stay here.

For professional publications of The Spa, physician's sample carton of the bottled waters with their analyses, please address W. S. McClellan, M D., Medical Director, Saratoga Spa, 155 Saratoga Springs, N Y

Note to an overworked doctor

BIOLAC is a complete liquid infant formula which saves you valuable time because there are no extra ingredients to calculate.

Biolac provides completely for all nutritional needs of young infants except vitamin C.

Prescribing Biolac reduces the possibility of errors or contamination in formula preparation since it requires simply dilution with boiled water as you direct.

NO LACK IN **BIOLAC**

Borden's complete infant formula

● Biolac is prepared from whole milk, skim milk, lactose, Vitamin B₁, concentrate of Vitamins A and D from cod liver oil, and ferric citrate. It is evapo-

rated, homogenized, and sterilized. For professional information, write Borden's Prescription Products Division, 350 Madison Avenue, New York City.

THE PHYSICIANS' HOME

Our part in this most critical period of our Nation's history is not on the battle front, but here on the home front.

Our job, in this insecure world, is to meet the needs of aged and worthy colleagues of our profession. In these trying times it is a responsibility which symbolizes a way of life among professional people.

The Physicians' Home has won the confidence of the Physicians of the State of New York. It must continue to serve.

Join with us in bringing comfort, security and happiness in 1943.

1942 Health Data

Many items of interest to physicians are discussed in the January issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company.¹

Concerning diseases among industrial policyholders of the Company in 1942, the *Bulletin* says:

Among the diseases which we might expect to be adversely affected by the war are the principal communicable diseases of childhood. In the last World War, the concentration of large numbers of individuals who had not acquired immunity to these diseases in childhood resulted in extensive epidemics among them. It appears that this has not occurred in the present war. At any rate, among the Metropolitan industrial policyholders scarlet fever, whooping cough, and diphtheria have recorded minimum rates, while the rate for measles is very little above its previous low. Likewise, there has been no serious outbreak of meningitis, such as occurred in the camps in the first World War.

Influenza and pneumonia, which claimed many more victims in the armed personnel than did battle casualties in the first World War, in 1942 actually played a minor role in mortality. The influenza rate of 4.2 per 100,000 is 44 per cent below the previous minimum recorded in 1938. Pneumonia in that year had a death rate of 50.6 per 100,000, and in the first five years of the decade it had averaged 66.5, last year the rate was only 29.4. The decline in the number of pneumonia deaths has been one of the outstanding features of the mortality record each year since the introduction of the newer forms of chemical and serum treatment. Although the decline in the rate continued in 1942, it was less marked than in the earlier years. This slackening in the decline is not surprising, since there is a point below which further improvement can be achieved only with exceptional effort.²

It is perhaps too much to expect that the 1942 rate for influenza and pneumonia even with exceptional effort can be maintained

or improved, but the full possibilities of the sulfa drugs and the electron microscope have not yet been explored or exploited, to name but two factors which may influence our expectations in this respect.

The death rate from tuberculosis, which is an excellent index to the health of the nation, continued its decline in 1942. Although the improvement was somewhat less than that between 1940 and 1941, it was twice that from 1939 to 1940. Other belligerents have not been so fortunate, and marked increases in the mortality from tuberculosis are reported from various European countries, even including Great Britain.

The venereal diseases constitute another health problem closely associated with the war. It is too early to judge how successful have been the steps hitherto taken toward the control of these diseases, for the current mortality reflects their prevalence in earlier years. It is interesting to note, however, that the rate for syphilis in 1942 among industrial policyholders was the lowest on record.

The venereal disease rate for 1942 was 10.5 per 100,000 contrasted with 11.5 for 1941 and 12.0 for 1940, including deaths from aneurysm of the aorta in this weekly premium-paying class of industrial policyholders. The implication of these figures seems to be that organized efforts to control the disease are proving effective. The weight remains to be seen, however, of the increase in the venereal morbidity rate noted in the age groups of 15 to 24 during the year 1942 and which will undoubtedly be reflected in the mortality statistics of subsequent years.

How have the rationing and the shortages of fuel affected the health of the country?

In the United States as a whole, males are the victims of exposure to excessive cold about four

Machines that Seldom Stop

DEMAND for medicinal supplies at the fighting front doesn't begin at eight o'clock and stop at five. In war there is no forty-hour week and casualties must be treated at all times—day and night.

Lilly employees feel deeply their obligation to produce a full share of essential therapeutic agents. Uppermost is the thought that machines must turn eight—sixteen—twenty-four hours a day to fill the needs of the allied armed forces.

How have the rationing and the shortages of fuel affected the health of the country?

In the United States as a whole, males are the victims of exposure to excessive cold about four

times as frequently as females. Two-thirds of the male deaths occur among men 50 years of age and older. Many of these older persons were probably suffering from arterial disease and were therefore more susceptible to the effect of exposure to cold.

It is particularly interesting at this time also to observe that some of the eastern states most critically affected this winter by fuel shortages registered death rates from cold below the general average of 2.8 per 1,000,000 observed in the United States as a whole during 1933-1940. The rates were 1.6 in both New York and New Jersey, 1.9 in Massachusetts, and 2.7 in Connecticut. Higher rates than the average occurred in Vermont (3.6), while the highest rates among those states affected by the wartime heating problem were recorded in Maryland (4.3), Rhode Island (4.5), and Maine (6.6).

The highest rates in the country prevailed in the mountain states of Nevada (24.0), Montana (14.9), and Wyoming (14.4). North Dakota (10.1) is the only other with a rate exceeding 10 per 1,000,000. The District of Columbia was lowest, with 0.6, and California was next, with 0.7.

This discussion has been limited to deaths due directly to extreme cold, actual freezing, frostbite, etc. In this connection the fuel shortage is a negligible factor. Its effect on the death rate from respiratory diseases, from homes set on fire, and from gas poisoning is another matter.

On the whole the picture for 1942, except for deaths and for those missing in military services, is encouraging.

These, in 1942, were nearly 40,000, including 11,000 members of the Philippine Scouts. While the

vast majority of the Army missing are prisoners, an appreciable number were killed in action or died of wounds. The exact situation in this regard is not known because the Japanese do not observe international conventions regarding the identification of prisoners. Even higher must be the proportion of deaths among naval personnel reported as missing.

Allowing for this situation, our military losses in 1942 probably were at least 11,000 and they may have reached 15,000. Since our military operations were predominantly naval, we lost more sailors than soldiers, the probable figures ranging from 6,500 to 8,000 for the Navy and Marines as compared with 4,500 to 7,000 for the Army. Our 1942 losses alone exceed all of those suffered by us in the first fifteen or sixteen months of the first World War. But it should be remembered that by the end of 1942 we had three times as many men serving overseas as on the corresponding date of the first World War and, moreover, this time we plunged more quickly into active and world-wide operations, both military and naval.

Concerning deaths in industry, apparently reliable figures for 1942 are still lacking, but deaths from motor vehicle accidents, according to the *Bulletin*, declined about 20 per cent among industrial policyholders and approximated 28,000 in the general population.

Plasma Therapy and Whole Blood Transfusion

A group of special lecturers is now available to bring to the medical profession the very latest information concerning plasma therapy and whole blood transfusion. The Council Committee on Public Health and Education of the Medical Society of the State of New York, the Office of Civilian Defense, and the Health Preparedness Commission of the State War Council and the State Department of Health, are sponsoring this program for the benefit of physicians in New York State.

These lectures may be arranged for as special single sessions or in connection with

formal courses or for special or regular meetings of county medical societies.

There should be a considerable demand for this program, and we urge all groups desiring this kind of instruction, so pertinent to the present war conditions, to apply early for speakers, in order that the committee may arrange its schedule at as early a date as possible. It is our understanding that some requests for this course have already been received from county societies, and we hope that those who have not already done so will avail themselves of this instruction.

For further details see page 557.

The Surgery of Patent Ductus Arteriosus

Nothing is more satisfying in the practice of medicine than the conversion of a previously hopeless disease into a complete cure. It matters little whether the miracle is accomplished by

purely medical means—viz., chemotherapy, vitamins, and hormones—or whether by the invention of a new surgical technic. A revolution of this type occurred recently in the congenital

cardiac lesion called patent ductus arteriosus, which had been regarded not only as incurable but as beyond any measure of relief.

Early in 1939 the first cure was reported by ligation of the patent ductus through a carefully devised transpleural technic.¹ At this time, it was pointed out by these pioneers that two dangers are inherent in the persistence of this fetal structure. One was cardiac decompensation resulting from what is virtually a large arteriovenous fistula. Criteria for recognizing this form of cardiac decompensation have been elaborated.² Cardiac decompensation was regarded by the early workers in this field as the prime indication for surgical intervention.

The second complication is streptococcus viridans endarteritis, which is easily engrafted on a patent ductus arteriosus. The inventor of the successful surgical technic and his coworkers once considered this complication a contraindication to operation.³ Nevertheless, other clinicians soon attempted ligation of the ductus so infected, but they met with failure.⁴ Two years later this fatal complication no longer proved the bar to successful ligation.⁵ Similar successes are accumulating in the literature. Thus both the

mechanical and the infectious features of this congenital malformation have been cured by a surgical method.

Unstinted praise should be lavished upon R. E. Gross, the pioneer technician, who brought about this remarkable transformation. Naturally, fellow-surgeons quickly followed the trail already blazed. A full measure of credit, however, is also due the clinician who extended the field of this surgical technic to include endarteritis of the ductus.⁵ Undeterred by previous interdictions and failures, he had the imagination and the persistence to visualize a complete cure by ligation of the infected ductus.⁵ The previously deadly streptococcus viridans infection, superimposed on the patent ductus arteriosus, has thus been conquered by the combined thought and operation of physician and surgeon.

Congenital Deficiency Malformations

The role of diet in the maintenance of health is too obvious to require elaboration. In the case of the pregnant woman diet is doubly important, for she must meet dual physiologic demands. Even at the cost of maternal decomposition, the fetus will inexorably seize all necessary available nutrients. In a recent study, Canadian observers¹ have demonstrated that a deficient maternal diet is responsible for an increased incidence of miscarriages, stillbirths, premature births, longer labor, and more frequent uterine inertia, together with other minor complications. Dietary regimen fulfilling the needs of pregnancy has been devised by the Canadian investigators and bids fair to better protect the interests of mother and baby.

Another risk of deficient maternal diets has recently been experimentally demonstrated in rats.² Congenital malformations have been produced in the offspring of female rats reared and bred on a deficient diet (Steenbock and Black Diet 1965). In spite of supplementary viosterol, the maternal nutritional deficiency induced by this diet produces in the offspring abnormalities characteristic of a disturbed developmental process. The abnormal newborn rats show shortness of mandible, shortness of radius, ulna, tibia, and fibula, fusion of ribs and of sternal centers of ossification, and syndactylism.

This diet is low in iodine content, an element important in thyroid physiology.³ Since a defective thyroid gland might adversely affect embryonic development, iodine was added to the basic diet—with no effect. Manganese deficiency has produced experimental chondrodystrophy in the chick embryo.⁴ For this reason, manganese was added to the basic ration, but it did not prevent the congenital bone lesions. Dietary supplements that proved to be effective were 2 per cent dried pig liver and the crystalline factors of the vitamin B complex. Two per cent alfalfa, rich in vitamins A, E, K, riboflavin, pantothenic acid, and pyridoxine, was not a preventive. Apparently some factor, present in liver and vitamin B complex, and absent in alfalfa, was the prophylactic agent. An important contribution made by these investigators was the evidence that therapy is futile if begun in the last third of pregnancy. A diet deficient in the first six months of pregnancy has thus been proved to produce irremediable defects in the newborn.

While the results of animal experimentation cannot always be translated into human terms, nevertheless an important lesson is implied. The obstetrician is not only the accoucheur but also the guardian of the fetus. As such, he must not only take pelvic measurements, blood pressures, examine urines, etc., but also must

studiously analyze and regulate the maternal diet. This will serve to lighten labor, to reduce

And The Officers

February 9, 1943

To the Editor:

At this time the question has been brought up in various quarters as to what meats, eggs, milk, and butter diabetics should be privileged to receive. The problems are answered in the accompanying recommendations of the Committee on Food Rationing of the New York Diabetes Association, which have been carried out at the request of the New York City Department of Health. It appears that, for the time being, the diabetics are well cared for except as far as the obtaining of fresh or canned vegetables and fruits is concerned.

However, if the rationing restrictions are tightened, inevitable problems will arise, and it is for this reason that the Committee on Food Rationing of the New York Diabetes Association has recommended that diabetics be requested to turn in their sugar ration cards and receive in their place such special privileges, in the future, as their disease calls for.

It may be noted that in England the sugar ration cards of diabetics have been exchanged for extra proteins—that is, especially, meats. Since there are about 7,500,000 diabetics in the United States, I am sure that you will readily appreciate the importance of this problem to the diabetic and to the community as a whole, and we hope that you will comment and give notice to the Association's recommendations in your columns.

CHARLES F. BOLDUAN, M.D., *President*
New York Diabetes Association, Inc.

FOOD RATIONING PLAN FOR DIABETICS

As Recommended by the Committee on Food Rationing of the New York Diabetes Assn., Inc.

1. The food requirements for diabetics vary among different patients as follows:

Carbohydrates:	150 to 350 grams
Protein:	60 to 90 grams
Fat:	60 to 100 grams

This should include at least a pint of whole milk daily.

Such a diet prescription should be made for each

patient by his physician and then the amount of meat, cream, butter, milk, fruits, and vegetables, and possibly other materials required, should be designated for the particular patient and ration cards issued accordingly.

2. Diabetics should surrender their sugar ration cards and for these receive extra ration cards, when necessary, for protein foods—especially meat—milk, butter, and fresh or canned vegetables and fruits.

3. The voluntary surrendering of sugar ration cards should be the first step toward registration of diabetics.

4. With regard to the diabetic's extra requirement for cream, this is not advisable, if, as supposedly will be the case, sufficient milk is available.

It is doubtful whether there exists in the diabetic a need for cream above that of the cross section of the population. If sufficient whole milk is available, it will meet the *minimal* butter fat needs. Special provision for cream should not be made.

5. Oleomargarine and other fats may replace butter for fuel needs to the extent advocated for normal individuals.

6. The main problem at present is that the diabetic obtain enough fresh and canned fruits and vegetables. Something should be done about the cost and the availability of these items for the needy. This is especially true of the so-called 5 per cent and 10 per cent vegetables—that is, the green vegetables.

7. The greatest necessity at the moment is to provide for enough bulk in fresh and canned vegetables to compensate for the concentrated foods usually predominating in the diabetes diet.

These are all the suggestions we have to make at the moment, but additional rationing might call for further changes.

Symposium—Surgery of the Prostate

RHABDOMYOSARCOMA IN THE LOWER URINARY TRACT

ROBERT W. HUNT, M.D., F.A.C.S., New York City

RHABDOMYOSARCOMAS of the lower urinary tract are rare. A careful search of the literature¹⁻⁶ reveals reports of only 26 cases—8 of the bladder and 18 of the prostate gland. Two additional cases are reported here. With one possible exception,⁴ all of the cases have terminated fatally. This most unfavorable statistical prognosis, plus the fact that over 50 per cent (16) of these cases were diagnosed and reported in the last fifteen years, would seem to warrant a discussion of the subject at this time. Discussion is further stimulated by the fact that the lesion is found in young patients, over 75 per cent of the growths having occurred in persons under 40 years of age. It is obvious that the ability to diagnose this lesion has improved, but it is equally obvious that treatment has not kept pace with the improvement in diagnosis.

Definition and Description

Rhabdomyosarcoma is the malignant variant of the rhabdomyoma. These tumors have their origin in striated muscle fiber,⁷ giving them an embryonal origin of mesoderm. The definite pathologic diagnosis is made by demonstrating evidence of myofibrillae with phosphotungstic acid stain and differentiates rhabdomyosarcoma from other sarcomas or myomas (Figs. 1 and 2).

Grossly, the tumor has been described as having the appearance of multiple polyps, or as resembling the structure of a hydatidiform mole. There is a smooth, nonulcerating, shiny, completely epithelialized surface. It would appear likely that once such a growth has been seen by the surgeon or cystoscopist, the diagnosis can be made clinically, so uniform are the gross descriptions of the tumors in the reported cases (Fig. 3).

The normal striated muscle from which these tumors arise has been demonstrated in the anterior part of the prostate.² Striated muscle fibers may be found in the region of the internal sphincter and adjacent area of the trigone. One can never prove the origin of these tumors, but it seems reasonable to believe that the neoplasms arise from the normally present striated muscle elements in the region.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 30, 1942. Part of a symposium on "Surgery of the Prostate."

From the Department of Urology, New York Medical School; Flower and Fifth Avenue Hospital.

Clinical Diagnosis

The initial manifestations were quite similar in all the reported cases, the patients presenting symptoms of dysuria, difficulty in voiding, and retention of urine. Hematuria is not an early symptom, for these tumors do not tend to ulcerate. On study, the clinician finds evidence of obstruction of the vesical neck by tumor, as demonstrated by urethrograms, cystograms, rectal examination, and cystoscopy.

These neoplasms usually grow very rapidly, necessitating early surgical interference. Examination of a biopsy specimen, obtained at the emergency cystostomy to relieve obstruction, will confirm the diagnosis.

Case Reports

The following two cases illustrate the typical clinical course of this tumor in the lower urinary tract:

Case 1 (Flower and Fifth Avenue Hospital).—R. D., a white male infant, born October 11, 1939, was a second child, both of the mother's pregnancies and deliveries having been normal. Nothing unusual was noted about the child until 72 hours after birth, at which time he showed evidence of cyanosis of the legs with some distention of the abdomen. Careful examination at this time revealed no evidence of intracranial injury or other injury or disease. These symptoms increased so that when the child was 5 days old there was a painful and distended mass in the suprapubic area, which was partially reduced by catheterization. No difficulty was experienced in catheterizing the child.

A cystogram was made 8 days after birth (Fig. 4). Examination of this showed a patent urachus, a large bladder with a filling defect, and deformity in the region of the trigone. From then on it was necessary to catheterize the baby because of acute retention. On the nineteenth day after birth, an indurated, tender area developed around the umbilicus, which ruptured spontaneously 3 days later and drained urine. This urinary fistula from the urachus provided satisfactory drainage of the bladder, and catheterization of the urethra was discontinued.

On December 19 (65 days after birth), a cystostomy was performed and suprapubic drainage was established. At this time, a nodular mass of very firm consistency was found covering the floor of the bladder, with the greater concentration around the bladder neck. A biopsy was taken of

FIG. 1. Microphotograph showing the myofibrillae stained with phosphotungstic acid.

FIG. 2. Biopsy of surgical specimen. Microphotograph showing the myofibrillae stained with phosphotungstic acid.

this mass and the case was diagnosed as rhabdomyoma. The child was treated symptomatically until February 13, 1940, at which time he was discharged from the hospital with a draining suprapubic sinus.

Fourteen days later (139 days after birth), the patient was readmitted with symptoms of diarrhea, vomiting, and fever. He was still draining through the suprapubic sinus. A consultation of the surgical, pediatric, and urological staffs was held, and it was decided that if a second biopsy confirmed the diagnosis, a total cystectomy, with removal of the prostate and transplantation of the ureters, would offer this infant the best chance, since at this time there was marked infection of the urinary tract with bilateral dilatation of the ureters (Fig. 5). It was also decided that the transplantation into the bowel would be more likely to prove successful if the loop of the lower bowel were prepared by separating it from the fecal stream by means of a colostomy. A second biopsy was done, the diagnosis being rhabdomyosarcoma.

Five and one-half months (172 days) after birth, total cystectomy and prostatectomy were done, and both ureters were transplanted to the skin at the same operation.

The child did unusually well after this procedure so that, 1½ months later, a transverse colostomy was performed and the lower bowel was irrigated with sulfanilamide solution and saline. Two and one-half months after the cystectomy (8 months after birth), a right ureterosigmoid anastomosis was done. The child continued to progress

favorably, and one month later a left ureterosigmoid anastomosis was carried out. Following this operation, the child ran a low-grade fever and showed evidence of continued urinary infection. Sulfathiazole therapy and transfusions had little effect. The baby ran a downhill course and expired 11½ months after birth.

An autopsy was performed. It was concluded that death was caused by chronic bilateral pyelonephritis with terminal pneumonia. The only evidence of remaining rhabdomyosarcoma was found in the region of the stump of the distal urethra which was left following cystectomy and prostatectomy. This finding was microscopic.*

Case 2 (New York Hospital†).—L. S., a 2½-year-old white boy, was admitted to the Brady Urological Foundation and the Pediatric Service of the New York Hospital on August 31, 1937.

The following history was given by the family: About six months before the patient's admission to the hospital (when he was 2 years old), he began to have pain on urination and retention of urine. There was no hematuria. The urine was examined by several doctors and reported to be normal. At that time the child entered a hospital for catheterization and cystoscopy. The cystoscopic examination revealed a bladder tumor.

* Autopsy performed by Dr. William Youland's staff. (Dr. W. Youland, Dr. F. Speer, and Dr. E. Khoury are publishing a pathologic study of the operative and autopsy specimens.)

† From the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital, and presented by the courtesy of Dr. O. S. Lowsley, director.

FIG. 3. Photograph of the surgical specimen, showing the bladder everted with the polypoid tumor mass on its floor.

FIG. 4. Cystogram of the bladder showing tumor on the floor and outlining the urachus.

Five months prior to his admission to the New York Hospital, a suprapubic cystostomy, with fulguration of the tumor, was done. This procedure was repeated twice thereafter, the last time being in July, 1937, one month before admission. A biopsy of the tumor removed was diagnosed as myoma. After the third operation the child was sent home with a suprapubic drainage tube in place. He was given three weeks of intensive x-ray treatment, which resulted in blistering his abdomen and caused him to be generally sick.

The tumor recurred rapidly after each operation and at the time of the child's admission to the New York Hospital it appeared to fill the entire bladder. At this time, he had pain on defecation and on attempting to void. Physical examination showed a well-developed but poorly nourished pale boy of 2½ years, fairly cooperative and alert but generally fretful. The general examination was essentially negative. Examination of the abdomen showed it to be soft and round, with no definite mass palpable. There was a suprapubic incision which drained urine and through which protruded a fleshy, red, irritated mass having the general appearance of polypoid tissue.

Complete laboratory studies were done, including platelet count, complete blood count, urinalysis, blood sugar, serum albumin and globulin, serum protein, urea nitrogen, and sodium chloride estimations. The only abnormal finding was a secondary anemia, with many white blood cells in the urine. This was treated by repeated small blood transfusions. Excretory urograms, done on the second hospital day, showed a functionless right kidney and beginning hydronephrosis of the left kidney.

On the eleventh hospital day, a right nephrostomy for drainage was done. The child withstood this procedure satisfactorily. He was given further transfusions, and on the twenty-first hospital day a total cystectomy and prostatectomy, with transplantation of the left ureter to the skin of the abdomen, was done. Gross examination of the bladder showed it to be entirely invaded by tumor, but there was no evidence of tumor in the prevesical spaces. Following this operation the child was given supportive treatment, including several more blood transfusions, sulfanilamide medication, and irrigation of his nephrostomy and ureteral tubes.

On the nineteenth postoperative day, the incision was reopened and a large amount of purulent material was found in the suprapubic region. This area was drained and irrigated with Dakin's solution. Thirty-eight days after the cystectomy, a small, firm tumor mass, about 1½ cm. in diameter, was noted in the incision. This grew rapidly and was removed six days later. Pathologic examination of the primary tumor and of this mass showed rhabdomyosarcoma in both instances.

About a month later, a second mass was removed, but another tumor mass appeared within five days. Approximately three months after the original operation, multiple tumor masses were noted under the skin, and the tumor mass from the incision had extended out of the anastomosis of the ureter in the skin. This mass grew rather rapidly and eventually closed off the ureter.

The child failed rapidly and expired about four months after his admission to the New York Hospital. No autopsy was granted.

Fig. 5. Excretory urogram showing the dilated kidney pelvis and ureters.

Discussion of Treatment

Although other sarcomas have benefited by roentgen therapy, rhabdomyosarcomas originating in this area have not been affected appreciably by such treatment. Indeed, in one of the reported cases, as well as in the second case presented here, roentgen therapy seems to have stimulated the growth of the tumor. Since the evidence is so strongly against these tumors being radiosensitive, one must conclude that roentgen therapy is definitely contraindicated. Such therapy has only increased the patient's symptoms.

At present, the only chance for a successful outcome appears to be early radical surgery. However, thus far one sees total failure in surgical procedures in rhabdomyosarcomas of the lower urinary tract. The question arises: "Why have these surgical attempts been failures?"

Generally speaking, discouraging results in surgery of malignant tumors have been due to one of three causes: (1) the tumors arise in locations where radical removal is technically impossible; (2) the growths metastasize early and before diagnosis; (3) early diagnosis is difficult and not often made. However, none of these seems to apply to the particular tumor under discussion.

Fortunately, the lesions arise in a location and extend in a direction most favorable for radical removal. Whether they originate in the prostate or bladder, the growths have been pedunculated into the bladder. The tumor, therefore, remains confined to the prostate and bladder for some time after symptoms are present—a fact well illustrated by both of the cases reported here. Metastasis to other parts of the body is exceptional. Metastasis by direct extension outside the bladder and prostate is slow to occur. Death usually results from obstruction to the urinary tract, with superimposed infection. The diagnosis, as a rule, is made early because the growth is invariably located near the bladder neck, and symptoms of vesical neck obstruction occur early in the course of the disease.

After careful analysis, one is forced to the conclusion that apparently radical surgery has failed because the surgeon has allowed too great a period to elapse between the time of diagnosis and the time of operation. This is borne out by the two cases reported here. In Case 1 the patient was operated upon five months after the diagnosis was made, and in Case 2, six months elapsed between the time of diagnosis and the time of radical surgical intervention. In the other cases reported, where radical surgery was attempted, a similar lapse of time occurred.

Comment

It is obvious that surgeons have hesitated to perform the radical operation of total cystectomy and prostatectomy because they have feared both the operation and its consequences. With increased experience with such operations, and greater success with ureteral transplants, will come increased assurance, and the hesitancy toward early operation will disappear.

It has been shown that rhabdomyosarcoma of the lower urinary tract is being diagnosed more frequently and at an early stage but that treatment has been 100 per cent unsuccessful. Success will be obtained by early radical operation. Furthermore, if the operation is done before dilatation and infection of the upper urinary tract have occurred, transplantation of the ureters will be successful, and the complications observed in the two cases reported here will be avoided.

Summary

Rhabdomyosarcoma of the lower urinary tract is defined, and its incidence of occurrence and symptoms are briefly considered. Two case reports are given. Treatment and the reasons for the failure of treatment in the past are discussed. It is concluded that early

radical operation will achieve the first successful treatment of this lesion.

TRANSURETHRAL PROSTATECTOMY

WILLIAM A. MILNER, M.D., Albany, New York

FAULTS with any operative technic are usually the basis for devising new methods for handling the same condition. Transurethral resection was devised largely, I believe, to relieve the mortality, morbidity, and economic distress associated with methods employed up to that time in the treatment of prostatism. Like all new things, it has enjoyed a wave of overenthusiasm followed by the inevitable reaction of criticism. It has only within the last few years reached a stabilized position in urology where it is definitely considered by all to be of value in selected cases.

Unlike many other surgical procedures, its scope of usefulness is almost entirely dependent upon the ability and "knack" of the operator. This "knack" or ability is largely due to the operator's knowledge of the appearance of the various types of tissue encountered at the time of operation. With this experience, sections can be cut rapidly and clearly with a minimum amount of trauma and its attendant bleeding. Good results can be assured because one is able not only to remove the obstructing tissue but also, in most cases, to resect down to the surgical capsule.

There are three characteristic types of tissue encountered: (1) the fibrous structure of the vesical neck, (2) the homogeneous granular prostatic tissue, and (3) the appearance of the prostatic capsule.

The presence of residual urine from three to six weeks postoperatively almost invariably means that some obstructing tissue has not been removed. Ninety per cent of the cases will completely empty the bladder one week after operation.

Postoperative discomfort with symptoms of cystitis is almost invariably directly proportional to the amount of necrotic prostatic tissue present. The majority of patients will void in amounts

varying from 150 to 450 cc. per voiding. This does not indicate marked urgency or frequency. One case, in which 114 Gm. were removed in one sitting of an hour and six minutes, voided dirty urine for about six months. At the end of that time, he passed a piece of necrotic prostate weighing 5 Gm., and the urine cleared within forty-eight hours.

The type of instrument employed depends entirely upon the personal whims of the operator.

In our practice, practically all types of prostates are handled by this method. An occasional case of carcinoma is referred for total perineal prostatectomy to those who we feel are extremely capable with this procedure. Of the last 600 prostates operated upon, only three two-stage suprapubic operations have been done, and one of these required a preliminary cystotomy for the removal of a large stone.

Preoperative care is handled as carefully as it would be for any other type of prostatic surgery. Blood chemistry and phthalein excretion must be within normal limits, if possible. Catheter drainage for two or more days is required in all cases having more than 4 ounces of residual urine on admission. All infected cases are treated with indwelling catheters and frequent irrigations.

The Murphy drip method of decompression is used in all overdistended bladders. We have used this routinely for the past ten years and have felt that a few cases were definitely benefited by it.

Four cases that had high nonprotein nitrogen and creatinines and low phthalein outputs have been resected. Three of the patients are alive and well from three to five years postoperatively, and the fourth case died of pneumonia four years postoperatively.

Each patient is given a light breakfast before going to the operating room. Preoperative sedation is rarely employed, for it serves but to depress the blood pressure, and the patient who is in the proper frame of mind concerning his operation is better off without it.

The anesthesia is now routinely spinal—of pontocaine, 12 to 15 mg. in equal amounts of 10 per cent glucose. The first 39 cases were done under caudal and trans-sacral block. An occasional case is done under sodium pentathal. Blood pressure usually remains fairly constant. Drops in pressure are usually adequately handled by *simple oxygen inhalation*, although ephedrine is used if necessary.

Operation

Vasectomy is done routinely. In carcinoma with metastases, intravaginal orchidectomy is done after the resection has been completed. The results from this operation have been most gratifying. Those who have had pain from metastatic lesions are completely relieved. In one instance, there was a marked regression of the original growth when the patient was examined four months later.

The operation is never prolonged more than one hour, and the average 25 or 30 Gm. prostate can be resected in thirty minutes. Many larger glands weighing from 60 to 90 Gm. are removed in one hour's total operating time.

Postoperative Care.—All patients are given a high backrest upon return to their rooms. During the first four hours after operation, 1,000 cc. of subcutaneous saline is given. The catheter is connected to a closed irrigating apparatus and irrigated only as necessary. Most patients are given soft diet the day after the operation and are allowed out of bed on the second postoperative day. The distension in the Foley bag is usually dropped to just a sufficient amount to make it a self-retaining catheter on the night of the day of the operation. In a few cases, this is not done until the following day.

The Foley catheter is removed on the fifth postoperative day, and patients living reasonably close to the hospital are sent home on their seventh postoperative day. Those who live some distance or who have complications are kept for a longer period.

Biweekly bladder irrigations are done for a period of from four to eight weeks until the urine becomes clear. Sulfathiazole in doses of 1 Gm. three times a day for four days is of great value in clearing up the last bit of infection. It does not work well, however, until about the fifth or sixth week, or until such time as epithelialization has taken place in the resected area.

Report of Cases

A total of 1,093 resections have been done on 1,020 patients. Two or more resections have been required in 73 cases, or 7.1 per cent, and three resections have been required in 7 cases, or 0.6 per

cent. No case in the last 977 consecutive cases has required any other type of surgery to relieve the obstruction.

Residual Urine.—Fifty-five per cent of the cases have had complete urinary retention. The rest have had varying amounts of from a few ounces to 30 or 40 ounces with overflow.

Age.—The oldest case resected was 94. The youngest case was 26. In the latter, only a congenital contracture of the vesical neck was resected, leaving the prostate intact. This boy gave a history of having always had a "bashful bladder," with three attacks of complete retention. There have been 6 cases over 90, 89 over 80 and 438 over 70 years of age, with an average age of 67 for the entire group. The youngest true prostatic was only 47, but had 11 ounces of residual urine, and 32 Gm. of prostate were removed at operation.

Tissue Removed.—The average tissue removed from each of the last 500 cases has been 27.5 Gm. The largest amount removed at a single sitting was 114 Gm.

Pathology.—Carcinoma has been found in 151 cases, or 14.8 per cent. Benign hypertrophies have appeared in 869 cases, or 85.2 per cent.

Not a few carcinomas of the bladder have been discovered associated with the prostatic pathology. One female who had a contracture of the vesical neck with twenty ounces of residual urine was completely relieved by resection.

Complications.—Emboli have occurred seven times, with 3 deaths.

Septicemia caused one death. Ruptured bladder with sepsis caused 2 deaths in the first 50 cases. Ruptured bladder as a result of an attempt to evacuate blood clots has occurred twice. Both patients were operated on immediately and one lived. The other was not a good risk for extensive surgery and died of shock twelve hours later.

Cerebral hemorrhage occurred in one case and bronchopneumonia in 2. Heart failure was the most common complication causing death. Hemorrhage has caused some deaths in earlier cases.

Incontinence which could not be cured occurred in 2 cases. One was an 86-year-old man with benign hypertrophy, and the other a 76-year-old patient with carcinoma. Neither has complete incontinence but both must wear pads. Practically all cases of incontinence are due to insufficient tissue being removed, so that secondary resection will cure them.

Morbidity.—The average total hospital stay is about two weeks. This includes those patients that have long preoperative stays to be prepared, as well as those who have complications and those who are virtually homeless and must

TABLE 1.—ANALYSIS OF RESULTS OF 465 CASES REPORTED OUT OF 550 QUESTIONNAIRES

be able to take care of themselves when they leave.

Mortality.—There have been 28 deaths, or 2.74 per cent, for the entire group. For the last 898 cases, there have been 15 deaths, or 2.1 per cent.

End Results.—Over a period of ten years, 550 cases were taken at random out of the group operated upon. Questionnaires were sent to each of these patients. The questions asked included the patient's general condition, the degree of discomfort in the bladder, the number of day voidings and night voidings, character of the urinary stream, and the character of the control of urine. Of the 550 questionnaires sent out, 465 were returned (see Table 1).

From the questionnaires sent to the 102 carcinoma patients, the results are given in Table 2.

Recurrence, exclusive of a few carcinoma cases, is the exception. Some early cases have required a second resection because insufficient

tissue was removed at the first sitting. Fifteen cases that had suprapubic prostatectomy have been resected with marked improvement.

Conclusions

1. In our hands, resection is the operation of choice on practically all prostates.
 2. The present lack of fear of prostatic surgery on the part of the patient is due largely to resection.
 3. Good results depend upon the ability to recognize tissue when it is encountered and to resect down to the surgical capsule.
 4. Postoperative cystitis symptoms are almost invariably due to leaving tissue to which the blood supply has been destroyed.
- All cases of postoperative incontinence should be cystoscoped and any tissue impinging within the external sphincter should be removed.
- No patient capable of living through his pre-operative preparation is too poor a risk to resect.

A SUMMARY OF ENDOCRINE EFFECTS IN ADVANCED PROSTATIC CANCER*

CHARLES HUGGINS, M.D., Chicago

IN SUMMARIZING our work on endocrine effects in advanced prostatic cancer, I wish to develop two points: first, that cancer of the prostate is often extremely sensitive to androgens (so that advantage may be taken of this fact in the practical therapeutic management of the disease); second, that the study of any disease, and especially cancer, is greatly expedited by developing objective laboratory methods of following its course.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, April 30, 1942. Part of a symposium on "Surgery of the Prostate."

From the Department of Surgery, University of Chicago.

*The investigation on which this paper is based was supported by a grant from the Committee for Research in Problems of Sex, the National Research Council.

It is necessary to discuss briefly certain enzymes capable of hydrolyzing phosphoric esters, the phosphatases. There are two of these enzymes, widely scattered through human tissue in small amounts, called acid and alkaline phosphatase because of certain chemical characteristics. These enzymes, however, are present in rich concentration in certain tissues: alkaline phosphatase in bone; acid phosphatase in the prostate gland of adult men and monkeys. This rich concentration of acid phosphatase in the adult prostate gland, then, is a secondary sex characteristic of a chemical nature. It was discovered in 1935 by Kutscher and Wolbergs. Elevations of alkaline phosphatase in serum occur in certain bone diseases when there is abnormal osteoplastic activity, such as Paget's

disease, rickets, and osteogenic sarcoma. Increase of acid phosphatase occurs in only one condition—cancer of the prostate with metastases to bone, as was shown by A. B. and E. B. Gutman and by Barringer and Woodard. When prostatic cancer is located in the bone marrow, the secretions of these cells find their way into the blood and are not readily disposed of, so that the acid phosphatase value increases above normal.

A step forward in this problem was the development by my colleague, George Gomori, of methods of staining the site of the phosphatases in tissue. While the prostate of the newborn child contains small amounts of acid phosphatase, the adult prostate contains large amounts of this enzyme. Carcinoma of the prostate likewise exhibits rich concentrations of the enzyme in the epithelial cells. It was thus recognized that prostatic cancer is a cancer of adult epithelial cells and not a reversion to a more primitive state.

In a series of 47 men with advanced prostatic cancer, it was found that 24 had elevation of acid and alkaline phosphatases, while in the other 23 men the enzymes were in the normal ranges. By frequent observation of the serum phosphatases of men who had far advanced prostatic cancer with elevation of the serum phosphatases, it was found that decreasing the amount or the activity of the androgens by castration or by administration of estrogen (stilbestrol, 1 mg. daily) caused a decrease of serum acid phosphatase values, whereas administration of androgen (testosterone propionate, 25 mg. daily) caused exacerbation of the serum phosphatase values and of the disease.

The beneficial results of decreasing the androgens were not limited to the serum phosphatases. Forty-five men with advanced and metastatic cancer have been treated by castration since October, 1939. When the cancer has been discovered early, total perineal prostatectomy has been done.

Certain benefits usually follow orchiectomy. Among the earliest changes are an increased appetite and relief of pain. These effects are often seen within several days following castration. They result in a gain in weight and an improvement in the anemia. Frequently there is a decrease of the primary tumor so that the hard, nodular, craggy prostate becomes smooth and soft and decreases markedly in size. Changes often occur in the bony metastases on roentgenographic examination, with the metastatic lesions usually undergoing increased calcification within several months after orchiectomy. This increased density is often followed by a stabilization in growth or by disappearance of the metastases

to x-ray examination. Other objective evidence of improvement that occurred in this series includes the disappearance in two cases of paralysis due to compression from metastasis in the central nervous system and in two other cases the disappearance of enlarged lymph nodes on the site of metastases.

Certain undesirable symptoms also occur, notably abolition of the adult sexual capacity and the onset of hot flashes similar to menopausal changes in women, and which likewise can be mitigated by estrogen administration (stilbestrol, 1 mg. daily by mouth for two weeks).

All in all, the improvement which occurs following orchiectomy in cancer of the prostate far outweighs the undesirable effects. It should be emphasized, however, that the results are not uniformly successful.

In the entire series of 45 patients subjected to orchiectomy, there have been 8 deaths, all in men with extensive metastases to bone. In 4 of these men, carcinomatosis was the principle cause of death, while in the others it was of secondary importance. From a clinical standpoint, 31 men have had a sustained improvement lasting as long as thirty months; 9 men have had a temporary improvement followed by recurrence of symptoms; and in 5 men there was no improvement following castration.

In 11 men of the group of 21 patients operated upon twelve to thirty months ago, there has been significant improvement. These patients are free from symptoms, acid and alkaline phosphatase values of serum are in or near the normal range, there has been complete or partial resolution of x-ray evidence of osseous metastases, and a great decrease is found in the size and in the stony consistency of the primary neoplasm on rectal examination. In 4 patients extensive osseous metastases have completely disappeared to radiographic examination.

The question of inactivation of androgens by estrogens in prostatic cancer as opposed to castration naturally arises. This type of endocrine castration as opposed to surgical castration is at first glance attractive, since it can be carried out without surgery and is financially economical. However, it is unsound, since the inhibition of the androgens by estrogens is not complete and a complete inhibition or elimination of androgens is the basis for the modern treatment of advanced prostatic cancer. Moreover, this partial inhibition is temporary, and estrogen must be administered for long periods of time. Furthermore, in many species the administration of estrogen to males for an extended length of time is in itself a carcinogenic. While it was first shown in this laboratory that beneficial results occur in prostatic cancer from both surgical castration or

estrogen administration, we feel that bilateral orchiectomy is the method of choice as a basic treatment in advanced or metastatic prostatic cancer.

LATE RESULTS FOLLOWING TRANSURETHRAL PROSTATIC RESECTION

LOUIS M. ORR, M.D., PALMER R. KUNDERT, M.D., and
FRANK J. PYLE, M.D., Orlando, Florida

THE question as to whether or not the results obtained from the transurethral resection of the prostate are permanent is one most commonly asked by the medical profession and the laity alike. A voluminous literature has accumulated during the past ten years on the subject of this method of relieving prostatic obstruction, but the majority of the writings have been given to the description of technic and more particularly to reports of large numbers of patients with extremely low rates of mortality. The majority of the end results reported up to this time concern the status of the patient only a few months after his operation. Almost nothing has been written on the subject of the condition of the patient in regard to his urinary symptoms many years after his surgery. How long was he free of frequency and distress? How long was he able to empty his bladder completely? Did he have to have other prostatic surgery before complete relief of symptoms was obtained? Did he consider the condition for which he had originally consulted his physician to be cured? These and other questions of this type have not, up to this time, been answered.

It must be stated at the outset that this study is not in any way to be construed as a comparative analysis of different methods of removing prostatic obstruction but is presented solely as a recounting of experiences in the use of the transurethral operation.

In an effort to answer some of these questions and to obtain as nearly as possible the true end results in a group of private patients subjected to prostatic resection, a study has been made covering a period of time between 1932, when the procedure first came into vogue, and the latter part of 1941.

The information which is to follow (Table 1) was collected through the medium of questionnaires sent to 483 private patients. Of these 483, 407 were traced. One hundred and fifteen were found to have died from within a few months to nine years or more after leaving the hospital. Data obtained on 76 were insufficient for tabulation on the results of their surgery. According to the patients' own statements, 160 of the total 252 who were contacted stated that they were satisfied with the results of their surgery. Nineteen stated that they were definitely dissatisfied because they had not been entirely relieved of their symptoms. Although they complained of having to arise more often at night than they thought necessary, 18 stated that they were partially satisfied. Intelligible replies were received from 252, and of this number 209 presented themselves for examination. Considering the transient type of population in the community in which this study was made, it is felt that this percentage of contacts was fairly high. Only those patients who were examined or who sent in intelligible answers are to be considered.

It is noteworthy that during this period between 1932 and late 1941, only 2 patients with prostatism of a sufficient consequence to demand surgery were refused operation because of associated complications. Based upon the criteria of acceptability for surgery, it is felt that a very large number of these patients would have been denied any type of prostatic surgery other than transurethral resection because of such complica-

tions as advanced cardiac disease, hemiplegia, diabetes, etc. The fact that many of these patients came to the community in extreme old age and in ill health also added to the hazards attending their surgery. The surgical mortality rate of this group was 8.3 per cent, which is higher than that quoted by other writers for most series of this type.
